In practical medicine undue attention ought never to be directed to any single sign or symptom. It is the association of symptoms that is of value in prognosis, and as a rule the ophthalmoscope and the sphygmomanometer ought to be used together. The clinical value of the actual number registered by the latter instrument can only be properly assessed after careful digital examination of the pulse, testing the urine, and thorough interrogation of the cardiovascular system as a whole. Unless there is some sign of cardiac weakness or of cerebral disturbance the restrictions placed upon the patient's general mode of life have as a rule little, if any, influence on the hypertension; but by interfering with the enjoyment of life and curtailing usefulness they create an anxiety neurosis which is far more harmful than the increased blood pressure. It is even worse still when on the supposition that the patient is suffering from dangerous disease he is sent to a spa, where strenuous measures are taken to lower blood pressure. Such treatment may be followed by disastrous results. A sudden fall in systolic pressure is apt to be accompanied by a relative increase in the diastolic, with engorgement of blood in the capillaries. One of the first signs of the upset in the physiological ratio of the systolic–diastolic pressures is the occurrence of haemorrhage from the capillaries of the retina. When that happens the prognosis is very serious, because it is often the prelude to a complete breakdown in general health. A disturbance in the physiological ratio between the systolic and the diastolic pressures is of much worse prognosis than a far higher hypertension in which the normal ratio is maintained and both pressures run parallel. When the hypertension is malignant the prognosis is grave. In these circumstances a form of Bright's disease is almost certainly present, the downward course of which is very rapid. The condition is invariably fatal, and death with uraemic symptoms usually occurs within a year. According to Ellis, in his Croonian lectures for 1941, the pathognomonic sign of malignant hypertension is the occurrence of papilloedema in both eyes, and in some cases the ophthalmoscope also reveals retinitis and haemorrhages.

When toxaemia and high blood pressure are of long duration the ophthalmoscopic picture of the fundus oculi becomes so lustreless that it resembles red velvet, and when the toxin is of special virulence loss of transparency and oedema of the retina become so very pronounced that capillary haemorrhages are usually seen scattered irregularly all over the eye ground. For example, the toxin due to pregnancy excites a very virulent reaction, and attacks eyes and kidneys simultaneously. Acute inflammation of both the retina and the kidneys is present from the outset, and the pathological changes seen in the eye with the ophthalmoscope are an index of what is taking place in the kidney. The inflammation of the retina appears suddenly, runs a violent course, and is characterized by such intense oedema that detachment may occur. Multiple capillary haemorrhages are always present. Both eyes are affected, and sight is impaired, and it may be lost very early in the course of the disease. In patients who have had no ante-natal supervision loss of sight may be the first warning of the approach of danger. The symptoms are often so overwhelming that the case may well seem hopeless; but the experienced physician knows that complete recovery is to be expected after the child is born. No better illustration could be given of the clinical aphorism that when a disease is due to toxaemia a favourable prognosis can always be given if the toxic agent can be wholly eliminated before organic disease of the blood vessels takes place. Unless that occurs, and the toxic agent is eliminated, recovery will be far from complete, and hypertension and albuminuria will persist. In these circumstances blood pressure is likely to remain high, and in course of time arteriosclerotic changes will appear in the retinal arteries and renal function will steadily fail.

Early Signs of Pathological High Blood Pressure

One of the earliest signs of pathological high blood pressure is constriction in the calibre of some of the branches of the retinal artery, and the degree of constriction is a reliable guide to the height of the systemic arterial hypertension. The constricted vessel usually takes a straighter course than is the case with a normal branch of the retinal artery, and when spasmodic constriction is accompanied by straightening of the course of the vessel it is as a rule evidence of organic disease. Loss of transparency of the wall of the retinal artery is another of the early results of persistent pathological hyperpiesia; consequently when spasm occurs in a branch of the retinal artery the outline of the vessel wall is clearly visible, and when spasm is complete the function of the retina supplied by the affected vessel is lost, and will not be restored until the spasm is relieved and the circulation of the blood is re-established. An analogous state of matters can occur in the circulation of the lower limbs—intermittent claudication: severe cramping pain in the muscles of the calf follows exertion, and compels the patient to rest until the arterial spasm passes off. Whenever that takes place the pain is relieved and the patient is able to walk. In both the eye and the leg an underlying constitutional state has existed long enough to produce vascular changes sufficiently serious to cause temporary obstruction of the circulation. When these vascular symptoms are persistent they are usually premonitory of the onset of arteriosclerosis, which is always pathological. Old age of itself will not cause it.

Arteriosclerosis

The earliest signs of arteriosclerosis are often seen in the fundus oculi; therefore in many instances we are able to study them in considerable detail during the patient's lifetime. When sclerosis occurs in the retinal vessels it is a fairly sure sign that it is also present in other organs of the body. Arteriosclerosis, however, is a most capricious disease. One organ may be affected dangerously while others escape.

Arteriosclerosis of the retinal blood vessels is similar to the arterio-capillary fibrosis of Gull and Sutton, and the ophthalmoscopic appearances have been admirably described by Marcus Gunn. The arteries are irregularly contracted, abnormally tortuous, and even the smallest exhibit a brightness of the central light streak which is very characteristic. The artery loses its transparency and becomes hard and rigid; consequently when it crosses a vein it not only conceals the latter from view, but also mechanically exerts so much pressure upon its walls that the flow of blood is hindered, and any sudden rise in blood pressure is apt to precipitate rupture and haemorrhage. In these circumstances the use of the ophthalmoscope is our best guide to the state of the cerebral blood vessels. There is a close relationship clinically as well as anatomically between the retinal and the cerebral blood vessels. Both of them arise from the internal carotid artery. When, therefore, arteriosclerosis develops both sets of vessels are likely to be affected simultaneously, but not necessarily to the same degree. Serious cerebral haemorrhage is more frequent than severe retinal haemorrhage. The vessels in the brain which rupture most frequently are of larger size than any in the retina. In the great majority of cases the true essence of retinal haemorrhage is capillary dysfunction rather than increased blood pressure acting upon a sclerosed artery. When, however, either retinal haemorrhage or cerebral haemorrhage occurs during sleep the patient has probably been dreaming, and the excitement of the dream has caused a rise in the general blood pressure. In these circumstances the haemorrhage is probably due to the rupture of a sclerosed artery either in the eye or in the brain, or in both simultaneously.

The Warning of Retinal Haemorrhage

Haemorrhage from the blood vessels of the retina is always evidence of disease and ought to be taken as a warning. Its causation should be investigated as thoroughly as would be the case after haemoptysis or haematemesis, but it is a mistake to take too gloomy a view of its significance. As an isolated sign it is not likely to increase the gravity of the prognosis regarding the patient's life, but if the bleeding is extensive the delicate structure of the retina may be injured so seriously that sight is gravely endangered.

Danger to sight depends upon the size and the site of the haemorrhage. In the great majority of medical cases the capillaries are probably the starting-point of retinal haemorrhage; but, when arteriosclerosis is advanced, rupture of an arteriole will determine a copious and destructive bleeding. When blood escapes into the inner layers—i.e., the conducting fibres—of the retina the clots are broken up by the nerve fibres. As a rule they are of bright red colour, small and flame-shaped. They generally disappear by absorption in about three weeks' time, but, unless the underlying toxaemia is eliminated, bleeding of this nature, once it begins, is prone to continue, and fresh haemorrhages take the place of those which have become absorbed. In this situation haemorrhages give rise to so few subjective symptoms that the patient may be unaware that anything is seriously wrong until his eye has been examined with the ophthalmoscope. When, on the other hand, the outer bacillary layer—i.e., the functioning unit—is implicated sight is seriously threatened from the outset by damage to the rods and cones, and the probability is that vision will be permanently impaired, if it be not altogether lost. These haemorrhages are deep-seated, and do not disappear quickly. They are dark red, and more or less circular. When the macula itself is involved central vision is obliterated, and the patient is unable to read or to recognize a friend on the street. Recovery of sight is not probable if the haemorrhage is deep-seated, and in any case vision is sure to be distorted—metamorphopsia—because of disturbance in the regular mosaic of the cones in the macula.

Types of Retinitis

High blood pressure, arteriosclerosis, and haemorrhage are the pathological forerunners of retinitis: but it is the quality of the blood that determines the distinctive aetiology in an individual case. Pathologists have described many varieties of inflammation of the retina; but the three most important clinical types—viz., the arteriosclerotic, the albuminuric, and the diabetic—are easily differentiated by an examination of the urine.

1. *Arteriosclerotic Retinitis*.—The ophthalmoscopy of this disease has been carefully described by Foster Moore, who was the first to suggest that it is a clinical entity distinct from albuminuric retinitis. In this form of disease persistent high blood pressure is always accompanied by extensive sclerosis of the retinal arteries. Its chief clinical characteristic is that the urine contains no albumin and there is complete absence of oedema. The patients are usually in late middle life, and are as a rule of stout build, of a fresh ruddy complexion, and of active habits. They enjoy speaking about their good health and often boast that they never require a doctor, while all the time their constitution is being steadily, though silently, undermined by the furtive advance of arterio-capillary fibrosis. Unless he has used the ophthalmoscope the family doctor may easily be put off his guard by the absence of albumin in the urine, and he is greatly taken aback when his patient is struck down suddenly by apoplexy or by a cardiac seizure. Mahomed insisted that high blood pressure rather than albuminuria is the pathognomonic sign of certain forms of Bright's disease, and some regard arteriosclerotic retinitis as a sign of chronic nephritis in which only the merest trace of albumin is found occasionally in the urine.

The ophthalmoscopic appearances vary according to the stage reached by the disease. Its onset is characterized by a reduction in the calibre of the arteries and by a loss of transparency of their wall. As the disease advances the veins are crushed where they are crossed by an artery, and many of the arterioles, especially those in the region of the macula, become twisted like a corkscrew. In the early stages the optic disk is pink from capillary congestion, but as the disease progresses it becomes pale and atrophic from sclerosis of its vascular supply. Small punctate haemorrhages, usually increasing in size and number, are seen scattered irregularly over the eye ground, and in addition there are numerous small circular hard-looking white spots situated for the most part in the central area of the fundus. The walls of the larger arteries become more and more opaque until at length the column of blood is concealed and the vessels resemble silver or copper wire. As time passes the lumen of the artery becomes almost obliterated and is now little more than a fibrous cord, and the area of the retina dependent upon it for its blood supply is starved, with the result that in the later stages of the disease patches of atrophy appear in the eye ground, and vision becomes permanently impaired.

2. *Albuminuric retinitis* can only be diagnosed after toxaemia, high blood pressure, and the presence of albumin in the urine have all been established. Both eyes are usually affected, but as a rule not to the same extent. The pathogenesis of the retinal changes depends upon high blood pressure and spasmodic constriction of the arteries; therefore the retinitis ought not to be regarded as a separate entity, but as an important and visible part of the general degenerative processes which are taking place in the kidneys. It is usually said that the patient is not likely to live more than two years after retinitis develops; probably that is true when applied to hospital patients as a whole, but there are many exceptions in private practice. The patient's general health does not become worse because his eyes have become affected, but the unfavourable prognosis after the discovery of the ocular signs is due to the fact that by the time the retinitis is detected the disease of the kidney is advanced and progressive. The earlier the retinitis appears, therefore, the worse the general prognosis, more especially if the disturbance in the eye coincides with the onset of uraemic symptoms.

Ophthalmoscopically the pathognomonic sign is oedema of the retina, and that is a sure indication that the reserve power of the kidney is being encroached upon. In the more acute cases white "cotton-wool" patches of soft-looking exudate are scattered over the fundus. The veins are distended and tortuous, and there are always signs of arteriosclerosis, accompanied by haemorrhages varying in both size and shape. They are scattered irregularly over the fundus, and are more numerous in the region of the macula. Lastly, one of the most characteristic features of renal retinitis is a star-shaped arrangement of minute white glistening spots round about the macula. This stellate arrangement of white dots, although very characteristic of albuminuric retinitis, is not pathognomonic of the disease, because it may occur in any form of acute neuroretinitis in which there is much oedema of the retina round about the macula

3. *Diabetic retinitis* occurs for the most part in the elderly—more especially in those who suffer from a comparatively mild form of glycosuria complicated by high blood pressure, by an appreciable degree of arteriosclerosis, and by the more or less persistent presence of a trace of albumin in the urine. It is almost never seen in the young, who are the chief sufferers from the acute forms of diabetes. The ophthalmoscopic picture differs from that of albuminuric retinitis by the absence of oedema and the "cotton-wool" patches of exudation. There are, however, in a typical case round yellowish-white plaques, situated for the most part between the papilla and the macula. As the disease advances these patches tend to coalesce and ultimately to form a ring surrounding the whole macular region. Haemorrhage is the outstanding feature of diabetic retinitis; consequently the ophthalmic surgeon is more concerned about the sight than about the life of the patient. The degree of vascular degeneration is the most important factor in the prognosis. The vascular changes are steadily progressive, and for the most part they fall upon the veins. Even the characteristic deep-seated punctate haemorrhages which are so suggestive of diabetes are apparently derived from venous radicles, and in some desperate cases massive haemorrhages from the veins flood the vitreous humour. These copious dense haemorrhages frequently occur during sleep, and the patient awakens to find himself blind in the eye affected. In some cases both eyes are implicated

Thrombosis of the central blood vessels of the retina is the ocular complication most to be dreaded when glycosuria is accompanied by albuminuria and when high blood pressure is persistent. Vision is lost suddenly, but several premonitory seizures usually occur before blindness becomes permanent. This condition ought always to be regarded as a serious warning of cardiovascular failure. The eye itself is also seriously compromised, because thrombosis is always accompanied by profuse retinal haemorrhage, which is often followed by the onset of secondary glaucoma. When that stage is reached the patient suffers from incurable blindness and more or less constant pain; consequently enucleation of the eyeball is the only treatment that can bring relief.

Commentary

To sum up very briefly, my endeavour has been to reach the following conclusions:

1. The interior of the living eye is a laboratory in which vital processes, both normal and abnormal, can be studied during the patient's lifetime.

2. Vascular changes such as capillary congestion, arterial degeneration, haemorrhage, and exudation can be seen with the ophthalmoscope; but the value of such observations in the prognosis of general disease cannot be properly estimated until they are correlated with such symptoms of general disease as high blood pressure, albuminuria, glycosuria, uraemia, and anaemia.

3. The debt which general medicine owes to ophthalmology cannot be fully appreciated until the physician examines the eye with the ophthalmoscope as habitually as he feels the pulse, interrogates the heart and lungs, and applies chemical and microscopical tests to the urine.

HAEMATEMESIS AND MELAENA

WITH SPECIAL REFERENCE TO BLEEDING PEPTIC ULCERS

BY

F. AVERY JONES, M.D., M.R.C.P.

Physician in Charge of Dietetic Department, Central Middlesex County Hospital

This paper reports results of treatment by prompt feeding and liberal blood transfusions in 171 consecutive admissions for recent frank haematemesis and/or melaena, between June, 1940, and December, 1942. They were treated in the dietetic wards of a modern municipal hospital serving a large industrial and poor residential district of Greater London. A careful study has been made of the cause of bleeding and of the type of case which proves fatal.

Diagnosis

Selected cases were gastroscoped soon after the haemorrhage, usually within a week or less. No serious complication occurred, although it is generally believed that gastroscopy is dangerous when performed shortly after bleeding. A barium meal was given as soon as the patient could start getting up, usually in the third or fourth week. If cirrhosis hepatis was suspected a hippuric acid excretion test of liver function was performed. A detailed history and an examination were recorded in every case. The final diagnoses are listed in Table I.

TABLE I.—*Final Diagnoses*

	Admissions			Deaths
	No	Male	Female	
Chronic lesser curvature ulcer found by x-ray, operation, or necropsy ..	30	26	4	7
Acute gastric ulcer found by early gastroscopy but not visible when radiographed later ..	21	15	6	0
Acute gastric ulcer found at necropsy ..	1	0	1	1
Pyloric ulcer	2	2	0	0
Chronic gastric and duodenal ulcers ..	5	4	1	0
Duodenal ulcer	47	36	11	3
Duodenal ulcer with gastro-enterostomy	6	6	0	0
Jejunal ulcer (gastro-enterostomy) ..	2	2	0	0
Localized jejunitis	1	1	0	0
Probable peptic ulcer with thoracic stomach	2	0	2	0
Peptic ulcer of Meckel's diverticulum ..	1	1	0	0
Haemorrhage complicating perforated gastric or duodenal ulcer	7	6	1	3
Acute gastritis	2	2	0	0
Carcinoma ventriculi	4	2	2	0
Leiomyoma ventriculi	1	1	0	0
Portal thrombosis—gastrostaxis	1	1	0	1
Cirrhosis hepatis	4	1	3	2
Uncertain (6 patients not investigated) ..	34	21	13	0
Totals	171	127	44	17

Gastroscopy was performed in 38 out of 51 cases which clinical and radiological investigations failed to diagnose. In 21 of these cases an acute gastric ulcer was found, and in 2 an acute gastritis. The remaining 15 remained undiagnosed. That is to say, in nearly two-thirds of the cases in which other methods failed gastroscopy provided a diagnosis. It is thus obvious that gastroscopy is of great assistance in achieving accurate diagnosis. The chronic gastric ulcers which were shown by radiographs had a much higher mortality than the acute ulcers which were only shown by gastroscopy. These acute ulcers usually healed within three weeks, and are being reported in another communication.

At this hospital all peptic ulcers are admitted to the dietetic wards, including those that are perforated. Seven cases were observed with both haemorrhage and perforation. This combined complication presented a difficult problem in treatment, with a high mortality. Three of the seven patients died.

Age Incidence

Gastro-duodenal haemorrhage is more often fatal in the elderly patient, and the age incidence, which is given in Table II, must be taken into account in comparing these results with other series.

TABLE II.—*Age Incidence of Cases of Haemorrhage from Proved or Probable Peptic Ulcer*

Age	Male		Female	
	No.	Deaths	No.	Deaths
10–19	1	0	0	0
20–29	4	1	1	0
30–39	17	0	3	0
40–49	32	1	8	0
50–59	34	2	13	1
60–69	27	5	10	3
70–79	5	1	3	0
80+	2	0	1	0
Totals	122	10	39	4

The proportion of patients over 60 is considerably higher than in previous series of haemorrhage from peptic ulcer—e.g.:

	Hospital	Period	Total No.	No. over 60
Bulmer (1927)	Birmingham General Hospital	1902–26	467	9 (2%)
Hellier (1934)	General Infirmary at Leeds	1926–32	212	15 (7%)
Cullinan and Price (1932)	St. Bartholomew's	1926–30	105	11 (10%)
Burger and Hartfall (1934)	Guy's	1921–30	137	13 (10%)
Scott (1940)	Western Infirmary, Glasgow	1936–40	110	18 (16%)
Present series		1940–2	161	48 30%)

There are three possible factors which may account for the higher age incidence in the present series. First, many of the younger patients may be in the Services and so be referred to Army hospitals; but this would not account for the apparent absolute increase in older admissions. Secondly, wartime conditions may have caused an increase in peptic ulceration among the elderly, and this theory is supported by an analysis of the admission book at St. Bartholomew's Hospital (18% over 60 in 1940-2, against 10% in 1926-30). Thirdly, general practitioners tend to send the older and more decrepit patients to municipal hospitals, where admission is certain; and my own experience has shown that in these hospitals one is confronted with problems in treatment in the very elderly which are seldom to be found in the teaching hospitals.

Treatment

Treatment was along the general principles described by Witts (1937). A drip blood transfusion at 40 drops a minute was begun if it was thought that further bleeding might endanger life. If the patient showed evidence of anoxaemia the transfusion was usually given faster and oxygen was administered at 6 litres a minute with a B.L.B. mask. In general most patients were transfused if the pulse stayed above 120 a minute, if the blood pressure fell below 90 mm. Hg, or if the haemoglobin reached 40%; but it was not found possible to follow any fixed set of figures rigidly, and each case was judged according to its own particular circumstances. The transfusions were liberal, and usually two bottles (1,080 c.cm.) were given, being repeated if necessary. With persistent bleeding, four or six bottles were sometimes required. In 12 patients the blood volume (5,000 c.cm.) was replaced at least once. Using the M.R.C. gas-mantle set, it was seldom necessary to cut down on a vein. This was a great advantage because repeated transfusions could be given into the same vein, and the simplicity of the method was a boon to the nursing staff. The patients received two-hourly purée feeds. One-third normal saline was given to allay thirst. The feeds were usually well taken, but occasionally milk feeds would be given if desired.

Purée Diet

6 a.m.	Cup of milky tea
8 a.m.	Porridge and bemax; thin bread-and-butter and jelly marmalade; cup of milky tea
10 a.m.	Cup of milk and biscuit
12 noon:	Minced meat, chicken, or steamed fish; mashed potato; purée carrot or cauliflower
2 p.m.	Egg custard or cereal pudding or apple purée; orange juice
4 p.m.	Cup of milky tea; three slices of thin bread-and-butter; bramble jelly; sponge cake
6 p.m.	Vegetable soup or minced chicken sandwich
8 p.m.	Milk pudding or cup of milk
10 p.m.	Cup of milk and biscuit

Milk feeds during the night if awake

One-third normal saline as desired between feeds on first day

Morphine was given on admission and whenever further bleeding occurred, fersolate 3 gr. t.d.s. when melaena had ceased, and ascorbic acid 200 mg. t.d.s. for five days and then 50 mg. daily. Antacids were not given as a routine, but calcium and magnesium tribasic phosphate was allowed for pain. The patients were reassured about the invariable constipation, and an enema was given after four days if necessary. Laparotomy for arrest of haemorrhage was undertaken on only three occasions, but partial gastrectomy or gastro-enterostomy was performed during convalescence if indicated by economic circumstances or by the type of lesion.

Results

In these 171 cases there were 17 deaths (10%). This series includes gastric tumours, portal varices, and portal thrombosis. In 161 cases of bleeding from proved or probable peptic ulcer there were 14 deaths (9%). Miller and Nicholson (1941) have analysed 1,396 cases, treated by prompt feeding, with a mortality of 3.1%. In view of such previously good results this series is most disappointing, and indeed contrasts depressingly with my experience at another hospital (Jones, 1939a). Obviously, with the type of case admitted to this hospital, gastro-duodenal haemorrhage still carries a severe mortality, which demands a careful analysis to discern the type of case that continues to be lost and to assess the value of surgical treatment. The crux of the problem is shown in the following table. Out of 14 patients who died nine had severe complications, nine were over 60 years of age, and nine had simple ulcers more than 3 cm. in diameter.

Table III.—*Details of 14 Fatal Cases*

Age	Sex	Clinical Complications	Type and Size of Ulcer
51	F	Admitted moribund	Acute G.U.; 1 cm.
62	M	„ „	Chronic D.U.; 2 cm.
67	M	Perforation	Two chronic D.U.s; 2×1 cm., 1×0·5 cm.
56	M	„	Chronic G.U.; 7 5 cm.
67	F	„	„ „ 5×3 cm.
67	M	Lobar pneumonia	Chronic D.U.; 2·3×4.5 cm.
62	F	Bronchopneumonia	Chronic G.U.; 6 cm.
60	M	Perforated appendix with general peritonitis 12 days previously	„ „ ?,size
42	M	Ascites hypoproteinaemia (laparotomy)	„ „ 10 cm.
53	M	(Laparotomy)	Chronic G.U.; 3×5 cm. Acute G.U.; 1×0 5 cm.
65	M	„	Chronic D U.; 5×3 5 cm.
25	M	—	Chronic G.U.; 3×2 cm.
72	M	—	„ „ 5×3 cm.
63	F	—	„ „ 2×1·5 cm.

Two patients were admitted moribund, and neither would have survived laparotomy. It is doubtful whether the acute ulcer in one of these patients would have been found if operation had been possible. Six patients had such grave complications or such severe associated diseases that surgical arrest of the haemorrhage was hardly feasible. General peritonitis from a perforated appendix, perforation of a peptic ulcer, lobar pneumonia or bronchopneumonia are themselves serious enough in elderly patients, and much increase the hazards of a gastric haemorrhage. Laparotomy during active haemorrhage was performed in three cases, but the patients died. In the remaining three cases the treatment remains debatable, but it is doubtful if surgery would have saved any of them except perhaps one—that of a young man of 25. At this age death from gastro-duodenal haemorrhage is so rare that surgery was hardly contemplated, and probably his heavy alcoholism tipped the scales against him.

The literature on bleeding peptic ulcers gives such a diversity of results for medical and surgical treatment that it is difficult to formulate treatment from them. The confusion is probably due to important variables in the different series, especially the proportion of elderly patients, their nutritional state, the incidence of associated disease, and the proportion of acute to chronic ulcers. It seems reasonable to analyse the type of case coming under one's care and to draw up rules for their treatment—rules which do not necessarily apply where a different class of patient is being treated. The problem is whether to continue to give prompt feeding and liberal transfusions, and when operation should be advised.

Prompt Feeding and Liberal Transfusion

There is no doubt that the mortality from bleeding has been reduced. It is still uncertain whether recurrences of bleeding occur more often with a liberal diet or large transfusions th
they did with the older regime of starvation and only sm
transfusions. To study these points the series has been compar
with that recorded by Cullinan and Price (1932) fr
St. Bartholomew's Hospital (1926-30). This report includ
only admissions for haematemesis that could reasonably
attributed to peptic ulcer, but cases in surgical wards were n
included. For comparison with this series the following ha
been excluded: patients with melaena only, with surgical co
plications—e.g., perforations—with gastric tumours, cirrho
hepatis, and portal thrombosis. Cullinan and Price's cases w
treated on a very restricted fluid intake and occasional sm
transfusions (300 to 500 c.cm.). In many of the fatal ca
on this regime there was extreme dehydration (Jones, 1939

Age	Cullinan and Price, 1932		Present Series, 1942	
	No.	Deaths	No.	Deaths
10–19	1	0	0	0
20–29 ..	12	0	4	1
30–39	15	3	13	0
40–49 .. .	29	6	28	0
50–59	37	6	40	2
60–69 . ..	11	4	31	6
70–79	0	0	7	1
80+	0	0	3	0
Totals .	105	19	126	10

The total mortality has been more than halved, althou
the scales are heavily weighted against the present series
the higher age incidence. It will be seen that below the a
of 60 the mortality has fallen from 15 in 94 cases to 3
85 cases. Above 60 the mortality has improved from 4 dea
in 11 cases to 7 deaths in 41 admissions.

Death usually occurs after recurrent bleeding and seld
with the first haemorrhage. The reduction in mortality m
have been effected either by decrease in the incidence
recurrent bleeding or by making the patient better able to wi
stand further haemorrhage. It is necessary to know the eff
of early feeding and liberal transfusion in the incidence
recurrent brisk bleeding. Again this series has been compa
with Cullinan and Price's figures.

Recurrent Haemorrhages

	Cullinan and Price, 1932		Present Series, 1942	
	No.	Deaths	No	Deatl
All admissions for haematemesis from probable peptic ulcer, excluding surgical admissions	109	19	126	10
Those which recurred . .	39	16	35	6,
Those which recurred more than once	21	12	23	6

With early feeding and big transfusions the incidence
recurrent haemorrhage has appreciably diminished, and neit
feeding nor transfusion can therefore be accused of promot
further bleeding. The reduction in mortality has been effec
partly because recurrent haemorrhages are less frequent
partly because when they do occur the patients are better fi
to withstand them. There seems every reason to continue
give prompt feeding and liberal transfusions.

Surgical Treatment

Cases in which surgical treatment is likely to be conside
fall naturally into two groups: first, when the cause
bleeding is certain; secondly, when it is obscure.

Known Causes

1. *Acute Gastric Ulcer.*—Although the haemorrhage from a
gastric ulcers can be exceedingly severe and protracted, the only
lost was admitted moribund, and died within a few hours. Fi
one cases of probable acute ulceration with only one death ar
against operation.

2. *Post-operative Cases.*—In patients with a previous gas
enterostomy the haemorrhage tends to be slow and persistent ra
than brisk, and probably in severe cases it may arise from a local
jejunitis. Such appalling difficulties may be found at laparot
that conservative treatment is justified.

3. *Haemorrhage with Perforated Peptic Ulcer.*—Haemorrhage with perforation accounted for 3 deaths among 7 cases which presented extreme problems in treatment. In one fatal case there were two kissing duodenal ulcers—one bled and the other perforated. If this combination is suspected at operation it would be advisable to perform a short circuit and pyloric occlusion, or a partial gastrectomy if the conditions are propitious.

4. *Duodenal Ulcer.*—There were 3 deaths among 47 admissions with duodenal ulcers. Only one could be considered as a death during treatment for haemorrhage. Again, with the great technical difficulties of operating on a penetrating duodenal ulcer a medical bias is justifiable, except when haemorrhage is extremely brisk or repeated and if the patient is over 50.

5. *Chronic Gastric Ulcers.*—The important mortality has been among the patients with chronic lesser curvature ulcers, with 7 deaths among 30 cases (23%). Considering the age, associated complications, and chronicity of the ulcers it is doubtful if any surgeon could have achieved a substantially lower mortality if all 30 cases had had early radical operation. Bohrer (1941) gives a mortality of 26% for bleeding gastric ulcers treated surgically. Nevertheless, it is in this group that timely surgery might save a few cases which would prove fatal in spite of continued transfusion. The clinical observations of grave significance are:

Thickened tortuous radial artery
Age over 50 years—5 deaths out of 18 (28%)
Severe pain preceding haemorrhage—5 deaths out of 12 (40%)
Pain persisting after haemorrhage—2 deaths out of 4 (50%)
Recurrent bleeding: once—6 deaths out of 12 (50%); twice—5 deaths out of 8 (60%)

By selecting cases which came partly or wholly within this group a reduction in mortality from bleeding chronic gastric ulcers might be effected by *early* operation, and this aspect is being further studied.

Diagnosis Uncertain

Sometimes one is confronted with an exsanguinated patient without a definite diagnosis, but the case will become operable only if it can be included in the indications given above. The length of history, the site of the pain, the food relationship, and the severity of the haemorrhage are all unreliable in deciding the position and nature of the ulcer. The necessity for continued massive transfusion is not in itself sufficient reason for operation. Four patients with acute gastric ulcers had repeated severe bleeding, and needed 11,340, 6,480, 5,940, 3,780 c.cm. of blood respectively, but with routine medical treatment the haemorrhage eventually stopped. A history of severe pain, especially for more than three weeks, is very suggestive of a chronic ulcer. The histories of the proved acute and chronic ulcers in this series have been analysed thus:

Recent Pain or Discomfort	Acute Gastric Ulcer	Chronic Gastric Ulcer
No pain or discomfort ..	8	1
Discomfort	7	2
Pain	7	15
Severe pain	0	12
Totals	22	30

It is legitimate in doubtful cases to try to clinch the diagnosis by screening with a thin barium emulsion or by gastroscopy. Therefore if the patient can be proved to have chronic gastric ulceration, or in exceptional circumstances chronic duodenal ulceration, and is over 50—and especially if there is thickening of the radial artery, history of severe pain, or pain persisting after admission or recurrence of haemorrhage—then operation may be advised. Nevertheless, to improve on medical treatment it is essential to have an exceptionally experienced surgeon, and a skilled anaesthetist available at short notice. If this is not forthcoming no physician need reproach himself for continuing with medical treatment.

Organization

To obtain the best possible results after haemorrhage from peptic ulcer, good organization is essential. The first requirement is an adequate blood bank. There is much to be said for nursing all cases in special dietetic wards, where the nursing staff can become very expert in all phases of treatment. The medical staff should be agreed on the routine management, and a treatment schedule in the wards is of value.

A follow-up of all proved chronic gastric ulcer patients is invaluable, for intractability can be discovered early and partial gastrectomy advised. In due course this must reflect itself favourably in the mortality rate for gastro-duodenal haemorrhage.

Summary

An analysis is presented of 171 cases of haematemesis and/or melaena personally treated by prompt feeding and liberal transfusions. There were 17 deaths (10%).

Peptic ulceration was the probable cause in 161 cases, among which there were 14 deaths (9%).

Early gastroscopy gave the diagnosis in nearly two-thirds of the *x*-ray-negative cases. Acute gastric ulcer is a relatively common cause of bleeding, but acute gastritis is rare.

Of the peptic ulcer subjects 30% were over 60 years of age —a much higher proportion than in previously published series.

Old age, severe complications or associated disease, and large ulcers were important factors in causing death.

Prompt feeding and liberal transfusions have decreased the incidence of recurrent bleeding.

The indications for surgery are discussed.

My thanks are due to the North-Western Blood Transfusion Depot for their liberal supplies of blood, to Dr. H. Pollak for his able assistance, and to Dr. R. Asher for his valuable suggestions.

PRIMARY BRONCHIAL CARCINOMA AT THE AGE OF 4 YEARS 4 MONTHS

BY

C. ELAINE FIELD, M.D., M.R.C.P.
First Assistant to the Children's Department, University College Hospital

AND

J. P. QUILLIAM, M.Sc., M.B., B.S.Lond.
House-physician, Children's Department, University College Hospital

Primary carcinoma of the bronchus is a condition that has attracted much attention in latter years, particularly on account of the increasing number of cases seen. Many authors have collected series of cases in attempts to discover whether this increase is absolute or only apparent. Those who hold that the rising number of cases observed is apparent invoke refinements of diagnosis—e.g., radiography, bronchoscopy, and biopsy—to support their contention; others maintain that the increase is absolute. Recently Menne and Anderson (1941) have published observations upon two series of necropsies in America, which they cite as evidence for the increasing frequency of bronchial carcinoma. In all probability there is both a real and an apparent increase in the incidence of the condition.

The growth commonly occurs in the age period generally favoured by carcinomata but with maximal incidence between 50 and 59 years, whereas the frequency of other cancers is maximal at an older age (Simons, 1937). In the age group 20–29 cases are seen from time to time; in the decade 10–19 Simons found only 6 cases in his collected figures (total 2,796). The period 0–9 years in his table shows only one case, and this in a boy aged 5 years (Hirsch and Ryerson, 1928). Beardsley (1933) reported a case of carcinoma of the lung in a female aged 10 months; and McAldowie described the clinical and necropsy findings in a boy aged 5½ months with multiple nodular growths in both lungs, but no histological examination was performed. To these 3 cases we would add the one reported below (see Table), which was histologically an anaplastic carcinoma of the bronchus in a girl aged 4⅓ years.

Beardsley quotes Nuscheler (1875) as referring to a case of carcinoma of the lung in a girl aged 7 years; and McAldowie quotes Ebermann, who found one case in his series of 76, in a child under 9 years of age. These references are unobtainable and therefore cannot be included in the above series.

Both Beardsley's and Hirsch and Ryerson's cases were notable for the fact that secondary lesions were found, in the lumbar region in the former and in the tibia in the latter, before lung mischief was diagnosed. In our case the lung condition attracted immediate attention, and it was not until the pre-terminal phase that secondary metastases were found clinically. The particular interest of our case lies in the age of the patient, the anaplastic nature of the growth, and the possibility of accurate diagnosis in the living.

Reported Cases of Carcinoma of the Lung for the Age Period 0–10 Years

Authors	Age at First Attendance	Sex	Duration of Illness from Onset of Lung Symptoms	Clinical Findings	Necropsy	Histology
McAldowie (1876)	5½ months	Male	5½ months	Wasting since birth	Multiple nodules in left lung involving pleura, with many adhesions. Multiple nodules in right lung without pleural involvement. Secondaries in mediastinal glands	No report
Hirsch and Ryerson (1928)	5 years	Male	5 months	Secondary tumour appeared in right tibia 16 months before lung symptoms	Primary carcinoma of right lower lobe. Secondaries in mediastinal glands, left lung, right upper lobe, and thymus, also left tibia	Bronchogenic carcinoma
Beardsley (1933)	10 months	Female	2 months	Secondary growth in lumbar region appeared one year before chest symptoms	Primary carcinoma in left lung involving pleura, with adhesions	Adenocarcinoma of left lung
Field and Quilliam (Reported below)	4⅓ years	Female	2½ months	Dyspnoea produced by large blood-stained pleural effusion. Terminally the neoplasm involved the rib spaces and anterior chest wall	Nodules of growth in collapsed right lung involving visceral and parietal pleura and chest wall. Metastases in bronchial, mediastinal, right supraclavicular, axillary, and coeliac axis glands	Anaplastic carcinoma of bronchus

Case Report

The child, a girl aged 4⅓ years, was admitted to hospital on Nov. 22, 1941, as an emergency case, having had an unproductive cough for 11 days and breathless attacks in the mornings for the last week. For 10 days she had had attacks of abdominal pain with nausea and vomiting. On admission the child was pale, with some cyanosis of the lips and nails and marked dyspnoea. Physical examination of the chest indicated the presence of a right pleural effusion, which was confirmed by radiographs. The effusion steadily increased, and aspiration gave 300 c.cm. of a deeply blood-stained fluid. Five further aspirations in the next seven days yielded 1,780 c.cm. of a similar fluid. The last aspiration was followed by an air replacement, which considerably relieved the cough and dyspnoea.

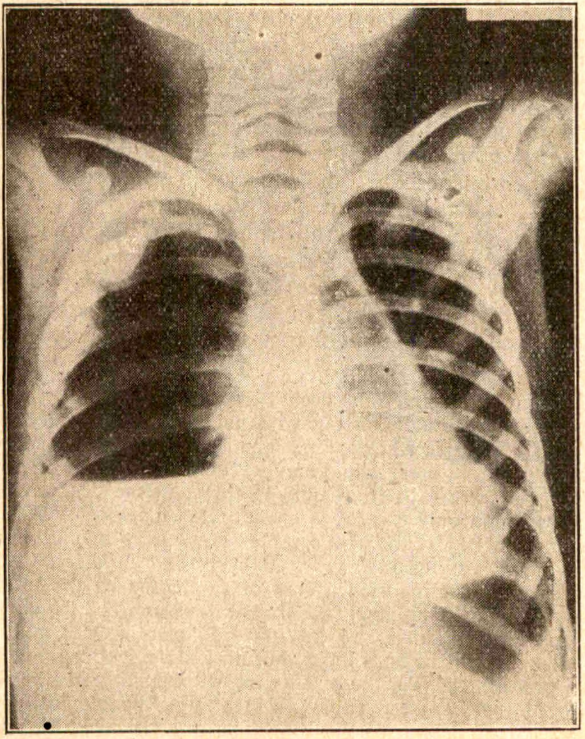

FIG. 1.—A radiograph of the chest taken after aspiration of the right side and air replacement, showing the right lung collapsed at the hilum and nodules of growth on the parietal pleura.

A radiograph of the chest (Fig. 1) now showed a fluid level on the right side at about the 7th thoracic vertebra, an artificial pneumothorax above this, the right lung collapsed at the hilum, and a nodular mass of growth at the periphery. So far no glandular enlargement had been detected and no mass felt in the abdomen.

On Dec. 13 thoracoscopy revealed the presence of numerous round, smooth, pink nodules of tissue of varying size up to 2 cm. in diameter, widely distributed over the parietal pleura. The lung was collapsed, and was covered with thickened but smooth pleura. A biopsy specimen was taken from one of the nodules.

Report on Fluid Withdrawn.—No tubercle bacilli were found. Guinea-pig inoculation was negative for Koch's bacillus. Culture was sterile. Examination of blood-clot showed a considerable number of cells in addition to red blood cells. Mesothelial cells predominated; some contained double nuclei, and an occasional mitosis was present. The remaining cells were mostly lymphocytes. The findings were suggestive of malignancy.

Report on Portion of Pleural Tumour.—The section showed an infiltrating anaplastic carcinoma with the histological features of a bronchial carcinoma. A neuroblastoma had been considered, but the characteristic " rosettes " were not present.

Progress.—A further aspiration and air replacement were carried out on Dec. 24 on account of respiratory embarrassment. The child's condition slowly deteriorated. The lower part of the right chest wall began to bulge and the rib spaces became filled in compared with the other side. Terminally, the ribs appeared embedded in the tumour mass. The final stage was marked by distressing bouts of coughing and dyspnoea. A week before death a fixed right supraclavicular gland was discovered; the day before death this gland was found to be further enlarged, and a gland was palpable in the right axilla. The child died on Jan. 28, 1942.

Pathological Findings.—The tuberculin patch test and the intradermal Mantoux test 1/100 were negative. Repeated red blood cell counts showed no marked anaemia, and 10 days before death the Hb (Haldane) amounted to 94%. The white cell counts showed a moderate polymorphonuclear leucocytosis, which increased terminally.

Post-mortem Examination

External.—Fairly well nourished. Right side of chest was enlarged and bulging anteriorly.

Respiratory System.—On reflecting the skin of the chest wall on the right side a firm white new growth was seen in all the intercostal spaces, infiltrating the subcutaneous tissue. It was continuous with tough white growth involving the whole of the parietal pleura, which was greatly thickened, measuring 1.5 cm. at its maximum width. In some areas the growth was soft and breaking down into creamy fluid. The right dome of the diaphragm was pushed down and invaded and greatly thickened by the neoplasm, which appeared on the under surface as large white nodules to which the upper surface of the right lobe of the liver was firmly adherent, but there was no infiltration. Behind the liver the growth extended downwards retroperitoneally to the level of the renal veins. This extension was formed chiefly by aortic lymph glands enlarged by growth. The heart and mediastinum were displaced to the left.

The visceral pleura of the right lung was similarly infiltrated to a maximum thickness of 1.2 cm., and the right lung was completely collapsed and fixed against the vertebrae. Four firm, broad, fleshy bands of the growth extended between the two layers of the pleura; they appeared like adhesions replaced with growth. On the cut surface of the right lung small areas of collapsed lung tissue were visible (Fig. 2), but the greater part consisted of white, somewhat soft growth. The bronchi contained muco-pus. Many bronchi were involved in the neoplasm, but this could not be seen actually arising from a bronchial wall. The hilar glands were much enlarged with white growth. The trachea and bronchi of the left lung contained muco-pus; the left hilar glands were not enlarged. Both lobes of the left lung were partly collapsed. Two small, flat, thin, round plaques were seen on the visceral pleura of the left upper lobe.

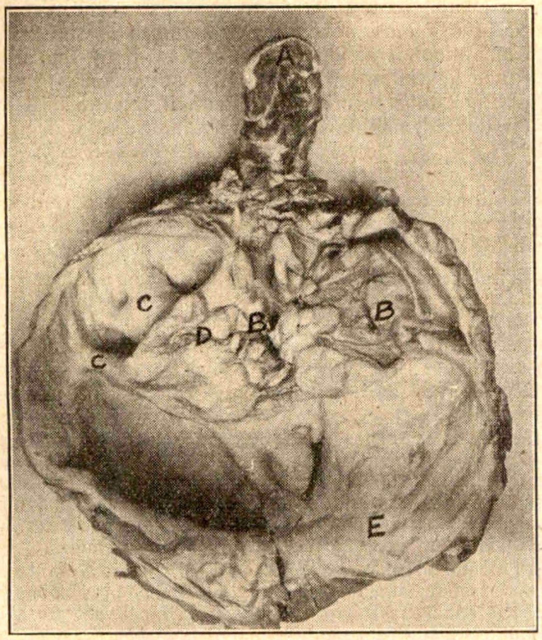

FIG. 2.—The neoplastic mass opened to show the collapsed lung containing nodules of growth, the parietal pleura greatly thickened and infiltrated, and bands of neoplastic tissue connecting the two. A, Tongue. B, Collapsed lung. C, Neoplastic bands. D, Nodules of growth. E, Parietal pleura.

There was considerable venous engorgement in the chest and neck veins. The lumen of the oesophagus was irregularly distorted by discrete mediastinal glands enlarged by secondary neoplastic deposits. The liver showed a pale mottling; its relation to the growth has already been described. Metastases were detected in the right bronchial, all the mediastinal, the right supraclavicular, one large right axillary, and the coeliac axis lymph glands. The right adrenal gland was displaced and partly surrounded by an extension of the neoplasm beneath the diaphragm, but the capsule of the gland appeared intact, a fact confirmed microscopically. The left adrenal was normal.

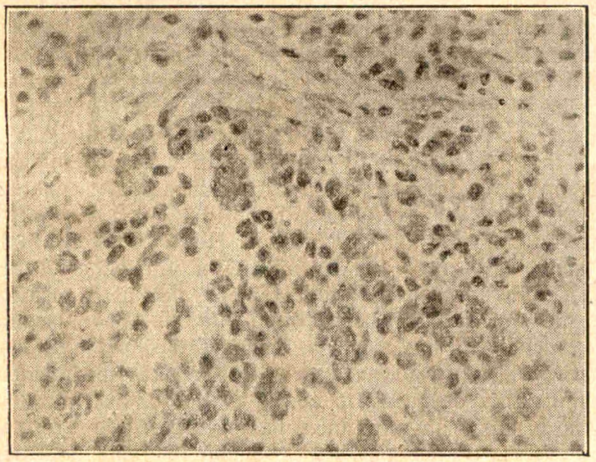

FIG. 3.—Photomicrograph showing masses of polyhedral cells and a few multinucleated giant cells.

Microscopical Examination.—Sections of the right lung and pleura and lymph glands showed a poorly differentiated carcinoma (Fig. 3) composed of masses of polyhedral cells varying in size and including multinucleated giant-cell forms in some areas. In many places where the tumour cells outlined the trabeculae of connective tissue they tended to be columnar-shaped. A large number of the cells were somewhat vacuolated; sections stained with mucicarmine gave an indefinite result. A few small areas of necrosis were present. Mitoses were not numerous.

Conclusion

The growth was an anaplastic carcinoma of the bronchus with extensive pleural involvement and metastases in the bronchial, mediastinal, right supraclavicular and axillary, and coeliac axis lymph glands.

We wish to express our thanks to Dr. W. J. Pearson for permission to publish the case and to Prof. R. S. Pilcher for performing the thoracoscopy and biopsy. We are indebted to Dr. D. M. Vaux of the E.M.S. Pathological Service for conducting the necropsy and reporting upon the fluid, the biopsy, and post-mortem material.

NASAL INTUBATION: DANGERS AND DIFFICULTIES FROM THE RHINOLOGICAL ASPECT

BY

A. R. DINGLEY, F.R.C.S.

Surgeon, Royal National Ear, Nose, and Throat Hospital

Pernasal intubation is to-day so often employed as a preliminary step in anaesthesia that it is perhaps not out of place to emphasize, from the rhinological standpoint, how necessary it is to have an adequate knowledge of the existing intranasal conditions in every case, in addition to a realization of the implications of the widely varying anatomy of the nose and of the factors limiting the safety of nasal intubation which nasal pathology can introduce. The fact that damage to the delicate structures of the nasal defensive mechanism occurs so relatively infrequently reflects great credit on the skill and care of the anaesthetist of to-day; but that harm can, and does, result cannot be denied, and serious consequences have followed the passage of a tube, either from faulty technique or from ignorance of the presence of intranasal conditions which should have debarred intubation. In other cases, less serious and often overlooked sequelae have manifested themselves later.

The nasal passages have highly important and essential physiological functions to perform: by warming, moistening, and filtering the inspired air they provide a highly specialized defensive mechanism for the protection of the respiratory tract; they ventilate the nasal sinuses, and provide drainage for them when necessary; the patency of the Eustachian tube is maintained via their channels, and the olfactory sense is dependent on their healthy state. These nasal channels, lined by highly vascular ciliated epithelium, are often tortuous, frequently obstructed by large sharp spurs, and always intolerant of abuse.

It is unwise to regard every patient as possessing a nose which is a safe channel for the passage of a tube, or all types of case as being suitable for nasal intubation. As unwelcome complications, although infrequent, can follow this method, it is well that it should be reserved only for those cases in which it is clearly indicated and in which other methods, unattended by the same potentialities, have proved inadequate. It is not contested that nasal intubation, which owes so much to the genius of Dr. Magill, is an excellent procedure in selected cases and in the hands of those who realize the need for respecting certain contraindications. The enormous number of successful cases bear witness to its efficiency, and the following observations are merely a plea for a realization of certain difficulties and dangers which are met with, and an attempt to help in surmounting them. The subject is approached purely from the rhinological aspect, and no particular knowledge of anaesthetics is professed. It is the oto-rhino-laryngologist, and not the anaesthetist, who is confronted with these occasional complications, not only because such complications are almost invariably the concern of his department, but because the cases most likely to be affected are those in which nasal and pharyngeal operations, and tonsillectomy in particular, have been performed.

It is clearly unwise to pass a tube through a nasal passage the interior of which is a closed book to the introducer; it is not enough to ask a patient if he can breathe through the chosen airway, as that will disclose neither a sharp spur nor an infected nose. More useful help can be gained by an examination with a headlight *after* shrinking with cocaine; this may reveal a passage in which trauma is unavoidable, and which not even the most gentle persuasion could negotiate with safety: trauma is the prerequisite of all intubation troubles.

Complications

Haemorrhage.—This may be caused by undue force being applied in a narrow nose or by coming up against an impassable obstruction: the highly vascular mucous membrane is abraded, and the seeds of possible infection are sown. In a few cases haemorrhage has been very considerable, and in one tonsillectomy case the surgeon was blamed because the patient lost as much as two pints of blood.

Infection.—This is secondary to abrasion of the mucosa, although it may be caused primarily by faulty aseptic technique. Though more likely to occur in an already infected nose—in which case an aggravation of symptoms will result—it may also be found in a hitherto perfectly healthy one. In tonsillectomy or septic pharyngeal cases infection is particularly likely to occur if trauma has taken place; but the causation in these cases is different, and it is, I believe, the *withdrawal* of the tube from an infected field over the abraded area in the nose which is responsible. It was the occasional virulent sinus infection after tonsillectomy in a war hospital that first attracted my attention, and I noticed that this sequence had occurred: haemorrhage from the intubated side of the nose, followed by an infection of the antrum on the same side, in cases in which radiographs and transillumination had shown the antrum to be healthy before operation. By withdrawal of the tube, on which have accumulated organisms and septic blood-clot resulting from the operation, and depositing these on the abraded mucosa or sinus ostia, infection is readily initiated. Such sinus or nasal infections greatly increase the patient's discomfort and prolong convalescence; they rarely clear up without intranasal drainage, and may necessitate a stay in hospital, in Service cases, of 4 to 6 weeks instead of the usual 7 to 10 days. Such nasal infections may encourage secondary haemorrhage from the tonsillar bed or nasal passage or lead to acute otitis media. It is indeed difficult to explain to the tonsil patient why the antrum should require puncture, the ear an incision, or the nose packing.

Adhesions between the two surfaces of the nasal passage, septal and turbinal, may follow if both of these have been traumatized in opposed areas.

Some Contraindications

(*a*) If the operation and anaesthesia can be in every way efficiently, safely, and satisfactorily controlled by other methods, nasal intubation is not the preferable method rhinologically.

(*b*) Large sharp spurs, marked turbinal hypertrophy, and gross septal deviations should be considered contraindications, particularly in cases of tonsillectomy or septic pharyngeal states. Purulent secretions and crusts, alar and vestibular infections, and large polypi should also debar the passage of a nasal tube.

(*c*) Septicaemic or very toxic patients are not suitable subjects for intubation; if intubated at all, the oral route is preferable, and particular gentleness is required, as a minimum of trauma to the nasal, laryngeal, or tracheal membranes is likely to be followed by a serious spread of infection.

(*d*) Tubes which have slipped into the oesophagus are likely to be infected, and are better not withdrawn through the nose or reinserted into the nasal passages, particularly if bleeding during introduction has occurred.

(*e*) In cases with a history of recurrent sinusitis the oral route is preferable.

(*f*) Cases in which one side of the nose is being operated upon are better not intubated via the remaining nostril; particularly if the lesion is an infective one, the oral route is again preferable.

(*g*) Children undergoing removal of tonsils and adenoids should not be pernasally intubated. It is unwise to pass a good-sized tube past a large adenoid pad; and, moreover, removal of adenoids, now often undertaken as the first step in the operation, is seriously interfered with by the presence of the tube in the nasopharynx. It is not difficult to remove tonsils with a tube through the mouth if intratracheal anaesthesia is desired, and this in no way interferes with adenoid removal.

Precautionary Measures

The following suggestions, most of which are well known but will bear repetition, are made in an endeavour to surmount some of the difficulties presented:

1. Careful sterilization of the hands, all instruments necessary for intubation, sprays, and lubricants is essential; these are best placed on a sterile towel spread over the patient's chest.

2. The nasal passages should be sprayed with 5% or 10% cocaine before anaesthesia is begun.

3. Inspection of the selected airway with a good headlight is advisable.

4. If there is resistance to the passage of a tube no attempt to force a passage is permissible. If much bleeding has followed the attempt the tube should be withdrawn and antiseptic ointment (sulphanilamide, for example) inserted. The tube should now be inserted, preferably by the oral route, though in some cases the use of the other nostril may be reverted to after inspection.

5. All blood-clot and secretions should be removed from the throat and post-nasal region in tonsil cases, preferably by suction, before the tube is removed; fragments of infected blood-clot are likely to be withdrawn along with the tube and deposited in the nose.

6. If it is known that trauma has occurred during intubation it is possible to withdraw the tube via the pharynx at the end of the operation. By grasping it with forceps as it lies in the posterior pharynx it can be withdrawn bent upon itself, from larynx and nose simultaneously; by this means the infected tube does not pass over the abraded mucosa. With soft tubes this manœuvre is simple; with more rigid ones it is difficult. It is possible to cut the tube in half in the pharynx, and withdraw it in two pieces; it is needless to add that this suggestion will not meet with universal approval in these days of rubber shortage; but, nevertheless, it is an easy way out if the need is imperative.

MAINTENANCE TREATMENT WITH DIGITALIS

BY

ALFRED S. ROGEN, M.D., F.R.F.P.S.

(*From the Department of Materia Medica and Therapeutics, University of Glasgow and Stobhill Hospital, Glasgow*)

It is a well-established clinical practice to recommend the continuance of a maintenance dose of digitalis for patients with congestive cardiac failure who have responded well to the drug. Gold (1941) stated that "only about 15% of cardiac patients owe to the habitual use of digitalis the fact that they are able to carry on with a reasonable degree of comfort. The reputation of the drug is not enhanced, to say the least, by its use in the remaining 85% of the cardiac population." In Stobhill Hospital there has for some years been a special cardiac clinic for the supervision of patients with cardiac involvement who, after residence in the wards, have been found suitable for out-patient treatment. It has been a general rule, when digitalis therapy has proved necessary, to ascertain the adequate maintenance dose and to continue its administration. In some instances this treatment has been carried on for over four years. Patients attend at regular intervals, and many of them take an intelligent interest in their treatment. It was thought that these patients were excellent subjects for determining whether, in view of Gold's statement, we had been unduly liberal in dispensing digitalis.

Experimental Investigation

Having decided on this investigation, the first 20 patients who attended the clinic on and after a certain date and who were receiving a maintenance dose of digitalis were chosen. Drug therapy was immediately stopped and no medication was given until there was some indication of ill-health. These patients, all of whom had proved most co-operative, attended the clinic every week. If objective signs of heart failure such as marked increase in heart rate, visible dyspnoea, cyanosis, or oedema appeared, it was concluded that the lack of digitalis was being felt. If, however, without objective evidence, the patient complained of not feeling well, he was given tablets containing lactose in order to make quite certain that the ill-health was due to increasing cardiac decompensation and not to psychological disturbance from want of medicine. Only when objective signs of failure appeared was digitalis therapy restarted.

The 20 patients varied in age (Table I) and in duration of digitalis administration (from a few weeks to more than four years).

TABLE I.—*Age Incidence of the Patients Investigated*

Age :	20–30	31–40	41–50	51–60	61–70
Number of patients	3	5	8	1	3

There was a definite history of rheumatic fever in all but three patients, in whom arteriosclerosis with hypertension appeared to be the aetiological factor. One patient with a history of rheumatic fever had a positive Wassermann reaction, while the others had no serological or other evidence of lues. All had been in-patients of the hospital with definite signs of cardiac failure. Auricular fibrillation was present in all but two of the series. The daily maintenance dose (Table II) varied from 1/2 to 4 gr. of the powdered leaf, which is the preparation utilized for all patients attending the clinic.

TABLE II.—*Maintenance Doses of Digitalis*

Maintenance dose (gr.) }	½	1	1½	2	3	4
Number of patients	3	2	2	7	4	2

Of the 20 patients 16 showed objective evidence of progressive cardiac failure before any complaint was made of ill-health or distress; in each case compensation had apparently been satisfactory the previous week. Such a rapid onset of recurrence of cardiac failure differs from the lengthy period of subjective upset which is the rule before a first attack of congestive failure.

TABLE III.—*Time Taken for Signs to Appear after Cessation of Digitalis Administration*

Case	Age	Maint. Dose (gr.)	Signs	Time in Weeks after Digitalis Stopped
1	45	2	C	5
2	38	1½	D O	8
3	41	½	D O	8
4	40	2	T	2
5	34	4	C T	11
6	49	½	D T	6
7	38	3	D T	2
8	27	4	O T	6
9	61	1½	D T	2
10	54	3	T	4
11	44	2	T	4
12	62	2	O	2
13	48	3	C D O T	5
14	47	2	T	4
15	29	3	T	3
16	24	2	D T	6

C: Cyanosis. D: Visible dyspnoea. O: Oedema. T: Marked increase in heart rate.

In this group the time taken for the signs to appear after the cessation of digitalis administration varied from two to eleven weeks, with an average of just under five (Table III).

Visible dyspnoea was the feature in 7 instances, oedema of the feet in 5, cyanosis in 3, and a marked tachycardia in 12. There was no correlation between the size of the maintenance dose and the length of the sign-free period, nor did the age or weight of the patient appear to influence the duration of the period.

The remaining 4 patients made subjective complaints—increased fatigue and a feeling of breathlessness—at an interval varying from two to six weeks after cessation of the digitalis therapy. No objective evidence to support their complaint was found in any of them. Accordingly the lactose tablets were given. In all four cases objective signs subsequently appeared—in one case in two weeks, in two cases in four weeks, and in one case in six weeks after the first subjective complaint. Visible dyspnoea was noted in all four cases, increase in heart rate in two, cyanosis in one, oedema in one, and liver enlargement in one. These signs appeared in all cases eight weeks after the digitalis had been stopped (Table IV).

TABLE IV.—*Time Taken for Appearance of (i) Symptoms and (ii) Signs after Cessation of Digitalis Administration*

Case	Age	Maint. Dose (gr.)	Signs	Time in Weeks after Digitalis Stopped	
				Subjective	Objective
17	39	1	D T	4	8
18	44	2	D C LE	6	8
19	70	1	D O T	2	8
20	50	½	D C	4	8

C :Cyanosis. D: Visible dyspnoea. LE: Liver enlargement. O: Oedema. T: Marked increase in heart rate.

In all the cases digitalis administration was restarted as soon as there was any sign of increasing cardiac decompensation. Evidence of recovery appeared within a week. This fact indicates clearly that digitalis therapy was essential for the comparative well-being of these patients.

Comment

From this small series of cases it seems reasonable to state that for patients with cardiac failure who have required digitalis for treatment in the decompensated state a maintenance dose of the drug is necessary.

I have pleasure in expressing my indebtedness to Prof. Noah Morris for his advice and assistance in the preparation of this paper, and to Dr. A. D. Briggs, medical superintendent of the hospital, for his interest.

Medical Memoranda

Multiple Foetal Adenomata of the Thyroid

The following case on which I operated six months ago in South Africa may prove to be of some interest.

A European woman aged 30 presented herself complaining of a disfiguring swelling in the neck. On examination the right lobe of the thyroid was found uniformly much enlarged, but there were no toxic or pressure symptoms. At the patient's request operation was undertaken. The right lobe and isthmus were removed, leaving only a very small piece of tissue over the recurrent nerve. The left lobe appeared only slightly enlarged, and was not disturbed. On section the specimen was found to contain dozens of nodules each slightly larger than a pea, and these on histological examination were shown to be foetal adenomata.

I believe this case to be unusual; for foetal adenomata are as a rule single, and it must be most exceptional to find dozens present in the same gland. One wonders whether, if this case had been left alone, each of these nodules would have developed into a typical colloid adenoma. How frequently do the common cases of nodular goitre have their origin in multiple foetal adenomata?

MODERN OPERATIVE SURGERY

(Carson's) Modern Operative Surgery. Edited by G. Grey Turner, LL.D., D.Ch., M.S., F.R.C.S., F.R.A.C.S., F.A.C.S. Third Edition. Volume I. (Pp. 1,041; illustrated. 50s.) London: Cassell and Co. 1943.

Prof. Grey Turner is to be congratulated on modernizing *Modern Operative Surgery* and producing, at the height of the war, a third edition of this work; congratulations are likewise due to the publishers on the high quality of their production. The standard is one of which they might well be proud in peacetime; in wartime it is really excellent. For long this textbook of operative surgery has, in our opinion, been the best work of its kind in English, and the late H. W. Carson did surgeons a great service when, towards the close of the year 1924, he first launched it. The present edition is dedicated to the late Rutherford Morison of Newcastle-upon-Tyne, to whom the editor refers as a "great clinician, master surgeon, and inspiring teacher"—and many readers would describe the present editor in the same terms.

Vol. I deals with anaesthetics, surgical tuberculosis, malignant disease, orthopaedics, operations on joints and tendons and bones, amputations, and the surgery of the breast and thorax and gastro-intestinal tract; also the surgery of nerves, blood vessels, and the spinal cord. Twenty-six well-known authors have contributed to the third edition, but the bulk of the work has been done by Prof. Grey Turner himself, and he is responsible for the greater part of the text. The new contributors to this edition are Messrs. A. J. Gardham, V. E. Negus, L. Carnac Rivett, W. E. M. Wardill, and Lambert Rogers: the last, who has written the section on the spinal cord, has by an oversight on the part of the editor been overlooked in his prefatorial reference to his new associates. As before, the indications for operation are stressed, and the details given are those of procedures which in the experience of the particular contributor have been found by him to meet best the special indications for the operation. Illustrations are good and helpful, and the text clear and in large type—in fact, the whole format is both attractive and inviting. We find little to criticize; but Lord Moynihan, who was such a great advocate of isoperistaltic anastomoses, would have been disturbed by the legend to diagram D of Fig. 378 on page 706, which incorrectly describes his Type II operation ("Moynihan I," by the way, is called "Roux") as "retroperistaltic" and Balfour's "anastomosis" as "isoperistaltic." (Reference to vol. I of Moynihan's *Abdominal Operations*, pp. 398 and 403, shows the Moynihan II operation as isoperistaltic.)

Perhaps the keynote of this book is best indicated by the editor's comment that a considerable period must always elapse before it can be said that a given modification, however striking or spectacular, is a real improvement rather than a mere change in technique, and that in surgery there can be no finality. Here we find presentations of methods which have stood the test of time and which have, in the experienced hands of the distinguished contributors, proved their value. For these reasons this work will be an invaluable guide to the young surgeon who has to decide whether to operate, when to operate, and what to do, especially if in such a predicament he is far removed from the advice and help of colleagues. It will be equally important to candidates for the higher examinations, while as a work of reference for practitioners it should find an honoured place on their bookshelves.

MEDICAL PROBLEMS IN SOCIAL WORK

Proceedings of the National Conference of Social Work. Selected Papers. 68th Annual Conference, Atlantic City, June, 1941. (Pp. 787. $5 or 33s. 6d.) New York: Columbia University Press: London: Oxford University Press.

Social work nowadays has a vast scope. The report of the American Conference held in 1941 contained 64 papers, selected from more than 150, and is a thick crown octavo volume. Many of the contributions are linked with national defence and social security; but, as might be expected, perennial problems of health and disease were prominent. James S. Plant's paper on personality adjustment in older children states clearly some of the major problems of the adolescent—such as the conflict between responsibility and dependence, the relation between the adolescent and the adult, his adjustment of his various autonomous personalities, and his search for a loyalty—and offers useful hints on their solution. Grace L. Coyle outlines the contribution of group experience and the development of older children, and points out the significance of the present tendency to form closely knit groups of contemporaries during early and middle adolescence. Hyman Lippman, writing on case work with adolescents in conflict with authority, declares that there is no place for punishment in this work but that its success depends on the choice of workers with suitable temperament and experience. In a paper on foster parents and the agency in the adoption process Elizabeth Harral examines the relation between the applicant and the agency and its significance. The place of the specialized consultant in child welfare services is examined by Mildred Arnold. In his prescription for breaking the delinquency-crime chain James V. Bennett somewhat depreciates the institution, but William J. Ellis is convinced that it is a full partner in the chain of agencies for preventive and external treatment, and describes the variety of the services performed by American institutions for the reformation of delinquents. Winfred Overholser points out some of the means by which mental disorder in the older age groups has been successfully treated.

A vital topic of these days, health service centres in industrial areas mainly engaged on war production, is ably dealt with by Kingsley Roberts; and John C. Leukhardt, advocating better housing as a health resource, declares that it will be attained only if the housing, health, and welfare agencies co-ordinate their attack. Another phase of the medical problem created by mass migration of workers is stated by Karl L. Schaupp in describing his experiences with the Farm Security Administration in California, which had to deal with a quarter of a million migrant labourers in 1938. Naturally the volume deals mainly with American conditions, but it will be of great help to directors of socal work in this country.

CINEPLASTIC AMPUTATION STUMPS

Cineplastic Operations on Stumps of the Upper Extremity. By Rudolf Nissen, M.D., and Ernst Bergmann, M.D. (Pp. 88; illustrated. 17s. 6d.) London: William Heinemann. 1943.

Cineplastic amputation stumps were introduced as early as 1898 by Van Ghetti. Attention was drawn to the procedure by Putti and Sauerbruch towards the end of the last war. English surgeons tried out the Italian method and came to the conclusion that the cineplastic arm stump had little practical value. This adverse conclusion was based mainly on the poor wearing qualities of the motor provided by the method employed and the relatively weak control of the artificial limb which is furnished.

The volume under review is interesting in that the authors put forward a strong case for the contrary view. In a small well-illustrated monograph they give the history and theory of the subject and outline the development of their own practice, which has been based on the muscle-tunnel technique of Sauerbruch. They define cinematization as a plastic operation on the muscles of a stump, thereby creating new sources and directions of muscular energy which, by the use of additional mechanical apparatus, will permit the artificial hand to perform movements approaching the normal. The authors are satisfied that the method can be usefully applied to the upper arm and forearm but not to the lower limb.

Sections of the book deal first with physiological and anatomical aspects of the question. The complexity of muscular action necessary to attain automatic balance in any movement is made clear. The practical bearing of the degree of shortening which a muscle undergoes on contraction is considered at length. In the chapter on the selection of suitable cases emphasis is laid on the importance of the mental attitude of the patient. The authors point out that the method is best adapted to double arm amputations, or to single arm amputations when the right limb has been lost. They point out, too, that a suitable stump should be free of scar tissue and painless, and, further, that the muscle should firmly adhere to the end of the bone and not overhang it. It is recognized that the power given by the motor provided is at best about 25% of the normal, and that therefore the procedure is unsuited for men doing heavy labour though well adapted to those involved in light hand-work.

The chapter on operative technique is clear and well illustrated. Various methods by which a muscle tunnel may be covered by skin are given in detail. The artificial limb suited for use with a motor is figured and some details are given. Drs. Nissen and Bergmann have employed the Huefner artificial hand for the purpose. No figures indicating the success or failure in their own cases are given. They state that according to the literature success has been achieved in from 68% to 10%. Their own work has been mainly carried out on civil injuries between 1927 and 1933, and on this account the quality of the stumps available was probably unusually good. Short chapters on the phalangization of forearm stumps and of the second metacarpal are given. A good bibliography of the subject is included, and this completes the practical value of a work which cannot fail to interest surgeons at the present time.

Notes on Books

The *1942 Year Book of Obstetrics and Gynecology* is dedicated to Dr. Joseph B. deLee, whose recent death removed one of the world's outstanding physicians. From 1903 to 1941 he was associated with the yearbook series, being editor of the *Year Book of Obstetrics* until 1917 and then editor of the obstetrical division of the present series until this last year. He was largely responsible for the success of this annual publication, in which his wise comments became such an outstanding feature. His co-editor of recent years, Dr. J. P. Greenhill, has now become sole editor, and has ably maintained the running commentary. There is much to be said, however, for a joint editorial staff. It would lighten the burden, and its comments could not be interpreted as the pronouncements of a dictator, however benign. The 1942 edition is arranged like its predecessor in two sections of approximately equal size, and each is subdivided in such a way that the latest papers on any given subject can be easily and rapidly discovered. A double index of papers and authors adds greatly to the value of the edition. The practitioner who wishes to find in the shortest time the latest views on the management of a posterior position, the treatment of abortion, toxaemia of pregnancy, the use of endocrine preparations in obstetrics and gynaecology, or any one of the other thousand and one problems of general or special practice will continue to find this yearbook his useful guide. It is published in England by H. K. Lewis and Co. at 19s.

No introduction is necessary to the eighth edition of Prof. Sydney Smith's classic on medical jurisprudence. The popularity of *Forensic Medicine : A Textbook for Students and Practitioners* is shown by the demand for a new edition in wartime less than three years after the appearance of the last. The text has been revised generally, and the various changes in the law governing poisons have been noted, as have also the additions to the lists of industrial diseases for which workmen's compensation is payable and which must be notified under the Factories Act. The publishers are J. and A. Churchill, and the price is 28s.

Dr. J. Vernon Braithwaite's little book on *Infant Feeding in General Practice* (Bristol: John Wright and Sons; 7s. 6d.) appeared first in 1930, and it had the great merit that its author was himself in those days a general practitioner, fully aware of the peculiar difficulties of the work. Now in a second edition Dr. Braithwaite reveals that he has changed to the ranks of the specialist, but his book remains a most useful and thoroughly practical volume, with an account of the feeding of the premature infant added; and a new chapter on deficiency diseases and their treatment has also been found necessary. The section on vitamins has required some expansion in the light of new discoveries. This book can be thoroughly recommended to all who have the responsibility of supervising the feeding of infants.

Home Guard casualties are bound to occur, even if invasion does not happen. *Guide to First-aid Treatment of Home Guard Casualties*, by Dr. T. H. Meek (H. K. Lewis; 4s.), is chiefly designed to show how the contents of the first-aid haversack for the Home Guard can best be employed. It is a pity that when omnopon—a dangerous drug—is mentioned its dose, except in one instance, is given as " grs." instead of " gr." The illustrations are peculiarly good throughout. The pneumatic tourniquet is pictured as being the one found in the haversack. It would be interesting to learn how this rather complicated type stands the rough wear of actual practice. For those for whom it has been prepared this booklet should be useful, but there is no index.

Preparations and Appliances

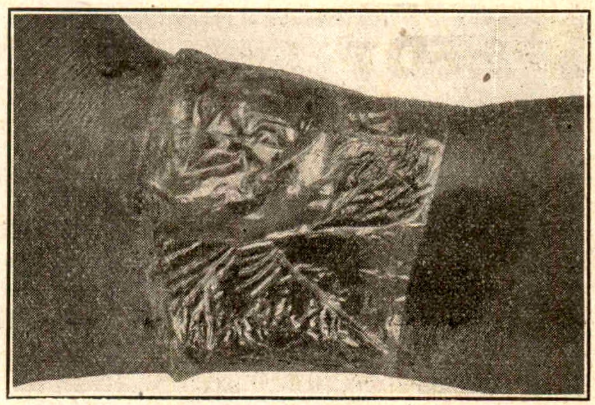
TRANSPARENT WRAPPING MATERIAL FOR DRESSING OPEN WOUNDS AND ULCERS

Dr. M. Ellis (Colonial Medical Service, Lagos, Nigeria) writes:

Transparent wood-pulp tissue of the type used for wrapping cigarettes has been used in brain surgery as a non-irritant, inert substance to prevent adhesions between brain and dura. It was considered that the non-irritant property might be of value if this material was used as a dressing for open wounds and ulcers. Thanks to the co-operation of our local Forces canteen, we obtained a supply of undamaged wrappings removed with care from packets of cigarettes sold there. We found that these pieces of tissue could be sterilized without damage by boiling in the standard ward sterilizer.

Routine of Dressing.—The wound or ulcer is cleaned or prepared in the usual manner as if a gauze or lint dressing were to be applied. We use either sulphanilamide powder or urea crystals actually in the wound. The wound is then covered directly with a piece of transparent tissue of appropriate size and this is secured at the edges by a bandage or strapping. The wound can be inspected at any time through the transparent wrapping and not uncovered until it is desired to change it. We have found that the wrapping can remain in place without tearing for about one week, and in the normal case we change dressings weekly. We have also found that the discharge from ulcers and wounds is very much less than with ordinary gauze dressings; in most cases the sealing of the wound by the transparent tissue contains this diminished discharge without trouble until the dressing is renewed at the end of a week. Some sloughing ulcers, however, still have enough discharge to exude beyond the wrapping. In these cases wool is placed round the edge of the wrapping to absorb this discharge. If this discharge is very plentiful, the dressing may be done twice a week at first, but very soon weekly dressings are sufficient.

In the photograph the wrapping material is seen covering an ulcer after having been in place two days—the retaining bandage has been removed. It will be observed that the transparent tissue has become slightly adherent to the skin around. I am indebted to Mr. Bird of the British American Tobacco Company for the following information. The transparent wrapping in use in the factory of the B.A.T. in Nigeria has the trade name of " rayophane " and possesses the property of sealing by the application of heat: the wrappings around the cigarette packets are sealed by heat. Although body temperature does not approach the temperature used for sealing in the factory, the constant warmth of the body is apparently enough to seal the tissue lightly to the skin and assist in keeping it in place. If the pressure of the discharge becomes excessive, it has no difficulty in breaking the seal and escaping into the wool. Through the courtesy of the B.A.T. we have now ample supplies of " rayophane," which they give to us from the scrap obtained from the factory, and this dressing is used as a routine both in the in-patient and out-patient departments.



To summarize the advantages: (1) The dressing is non-irritant and simple to apply; (2) the wound can be inspected without uncovering at any time; (3) the amount of discharge is much reduced—a possible corollary to this is that the smell in the ulcer wards is very much reduced now; (4) a tremendous saving of dressing material; (5) we believe that the rate of healing is increased by the dressing.

I am indebted to the Hon. the Director of Medical Services, Nigeria, for permission to publish.

LIVER EXTRACTS AND THEIR BIOLOGICAL EFFECTS

Since the discovery of the therapeutic effect of liver in pernicious anaemia it has been the aim of the pharmacologist to produce ever more concentrated extracts with the ultimate view of synthesizing the active principle. Clinicians, on the other hand, always on guard that the chemist in his rejection of unnecessary molecules should not render his remedy less potent, suspect that preparations become less active when they exceed a certain degree of concentration. The work of Subbarow and Jackson[1] suggests that the therapeutic potency of liver extract depends upon one principal factor which, if given in sufficient amount, can alone bring about a remission, and several subsidiary factors which, themselves without anti-anaemic effect, yet intensify the therapeutic efficacy of the extract. A recently published investigation[2] from Copenhagen throws some light on these subsidiary factors and their relation to the anti-anaemic principle. Barfred began his research in order to elucidate the causes of the disagreeable effects so often observed after injections of liver extract. He found that these reactions occurred especially with the use of preparations containing a relatively high amount of dry substance. He showed also that extracts rich in dry substance are highly toxic to mice, and that by employing a preparation 1 c.cm. of which was not lethal to mice it was possible to avoid most of the unpleasant reactions in patients with pernicious anaemia. This led to a study of other biological effects of liver extracts, with interesting results. Confirming and amplifying the work of previous workers, Barfred showed that certain liver preparations were capable (1) of increasing the volume and HCl content of the gastric secretion of normal and achlorhydric subjects, (2) of producing positive intracutaneous reactions, and (3) of inducing leucocytosis. The factors responsible for these effects have certain features in common, such as solubility in butyl alcohol and resistance to boiling and action of erepsin. An attempt was made to identify the substances responsible for these biological effects. Histamine, acetylcholine, adenosine, nicotinic acid, and other members of the vitamin B complex were studied, and it was shown that not one of these substances taken singly could produce all the subsidiary effects of liver extracts, although it was possible that a combination of the first four might. It is evident, however, that the subsidiary actions of liver extracts are not peculiar to this organ, as an extract of the thymus gland prepared in the same way produced the same results without any influence on the course of pernicious anaemia. Of interest for the future synthesis of the anti-anaemic principle is the finding that prolonged treatment of potent liver extracts by erepsin did not diminish the anti-anaemic potency, suggesting that the principle is not a simple polypeptide.

The subsidiary substances found in the butyl alcohol solution have no effect on pernicious anaemia, but by the use of the double reticulocyte reaction introduced by Minot and Castle it was shown that they increased the response obtained from the use of the residue left after treatment with butyl alcohol. If by further concentration of an active liver extract the stimulating effect of HCl secretion was abolished a reduction of the anti-anaemic effect was invariably found. This indicates a method whereby the limit to concentration can readily be determined. It also has led Barfred to put forward the interesting hypothesis that the gastric factor may be of importance in stimulating the stomach to produce the intrinsic anti-anaemic factor. With highly purified extracts containing but little of the subsidiary substances the therapeutic effect would be due merely to the haemopoietic principle contained in the extract. With less concentrated preparations, on the other hand, the patient would derive benefit not only from preformed anti-anaemic substance but also from the extra amount of intrinsic factor secreted by the stomach under the influence of the gastric factor contained in the extract.

The painstaking investigations of Barfred, while of considerable theoretical interest, may lead to results of some immediate practical value in providing a method for determining the optimal limits of concentration of a liver extract. It is obvious that all extracts should have some stimulating effect on the gastric secretion, thus limiting the degree of concentration upwards. At the same time they should be so purified that a dose of 1 c.cm. is not lethal to mice, thus ensuring that unpleasant reactions in the human subject are reduced to a minimum.

SOME PROBLEMS OF MEDICAL EDUCATION

Last year, following a request from the Interdepartmental Committee on Medical Schools, the Council of the British Medical Association set up a compact committee of fourteen to prepare evidence, and the result, under the chairmanship of Prof. Sydney Smith of Edinburgh, has been the memorandum printed at page 702. It is a clear and concise report, moderate and constructive in tone. While covering the five specific points referred to it, the committee goes into some broader considerations, recognizing that, although the organization of medical schools and of the facilities for clinical teaching poses problems of its own, the matter should be studied not as a thing apart but in relation to the whole question of the future organization of medical services. The problem is one not merely of devising methods of linking the present voluntary and local authority hospitals for the purposes of medical education, but of considering the place of the teaching hospital in the future hospital service and the method of associating other types of hospital and medical institutions with the teaching hospital. The method of recruitment to the profession and the needs of practitioners of the future, whose conditions of work may well differ from those we know to-day, must also be kept in mind.

Starting with the axiom that a medical teaching centre should be one from which medical education, both undergraduate and postgraduate, and research are organized for an area, the committee lays down general criteria to which the centre must conform if it is to fulfil its important functions. This conception of a medical teaching centre is elaborated under several subheadings. The memorandum next sets out desiderata in respect of the teaching staff, their selection, appointment, and status, and then passes to the question of how far general practitioners might assist in the training of medical students. Two frequent complaints are succinctly noted: one is that the future family doctor is not given knowledge that he will find to be essential in his daily practice; the other is that the newly qualified man may enter general practice without any previous instruction in his ethical relationships with his patients and his colleagues or in his rights and obligations under the Health

---

[2] *Acta med. scand.*, 1942, Suppl. **131**, 1.

Insurance and other Acts of Parliament. To meet these criticisms the committee, aligning itself with earlier declarations by the B.M.A., holds that medical education would be assisted if suitable general practitioners were invited to advise on, and be associated with, the training of the student. Further than this, medical faculties or medical school committees might with advantage include general practitioners in their membership to advise on the curriculum so far as it relates to matters of importance in general practice, and to ensure that adequate attention is given to them. With regard to teaching methods in general, the memorandum stresses the need for relating the medical curriculum to the organization and requirements of medical practice. Changes are in the air, and in many respects the present methods of teaching will not produce doctors competent to reach the standard of practice that will be demanded in the future. This leads to the point that students should be taught the fundamental principles of health and disease rather than the diagnosis and treatment of separate diseases. Many doctors to-day find difficulty in keeping abreast of modern medical progress because they did not have a sufficient grounding in their student days. The function of the future practitioner in maintaining health as distinct from treating disease should also be provided for in the curriculum. Again, for most students the time occupied in watching major operations could be spent more profitably in acquiring under supervision practical experience in those surgical procedures that are likely to fall to the lot of the general practitioner.

To many people in 1934 there was something novel in the recommendation in the B.M.A. Report on Medical Education that every student should be required to spend some time in practice under supervision before being allowed to embark on independent practice. The idea has made much progress since then, and the present memorandum, noting the movement of opinion, discusses two different views on how to achieve this end. It agrees with the Medical Planning Commission that the period spent in practice under supervision should occur after the final examinations have been passed but before the licence to practice independently is granted; it should be essentially a time of instruction combined with some responsibility, but no formal examination should be required at the end of the year. (The General Medical Council, while favouring this proposal in the public interest, has pointed out to the Interdepartmental Committee that it may involve amendment of the Medical Acts.) Then follow two sections on post-graduate courses—those for general practitioners and those in special subjects. It is recommended that, in a national scheme of medical service, periodical "refresher" courses for the G.P. should be compulsory, and that steps should be taken to satisfy varied wants by making use of both voluntary and local authority hospital resources on a systematic basis, the instruction being given by teachers familiar with the G.P.'s difficulties and in sympathy with his outlook. The memorandum closes with a brief glance into the future of medical practice, both general and special; a tentative estimate of the number of general practitioners who might be needed after the war; and a note on the selection of medical students—the human material from which the future doctors are to be fashioned. Two main points are put forward: one is that better care should be taken by the medical schools to exclude from our profession men and women who, though able to pass the examinations, have not the aptitude, character, or staying power needed for the arduous and responsible duties of a medical practitioner. The other is that there should be a recognized arrangement for picking students, with the object of recruiting to the profession any boy or girl, from whatever section of the community, who shows a natural inclination for medicine and who has the character, health, and intelligence that a successful medical career demands. As a natural corollary to this comes the final recommendation that funds be made available to help selected candidates who could not otherwise join our ranks.

PLAGUE ABROAD

We have Defoe and the sites of plague pits to remind us that infection with the *Pasteurella pestis* was once one of the perils of our land. While we remain mercifully free from the pest, it is well to recall that it is a public health problem in many parts of the Empire, and also in America. Reports for January–October, 1942,[1] showed cases of plague in Basutoland (10), Kenya (703), Uganda (338), Egypt (3), Madagascar (92), Morocco (349), Union of South Africa (68), India (854), Palestine (5), Azores (1), Argentina (25), Brazil (9), Chile (1), Peru (102), and in four provinces of China. Two young boys from different localities in California died from the disease in 1941.[2] Fortunately the West Indies have been free since 1921. It is evident, however, that plague is one of the main health problems of some of our colonies. From February, 1941, to February, 1942, 547 cases of plague (416 bubonic) were admitted to the two civil hospitals in Nairobi,[3] with 354 deaths. It is the native population which has been involved in nearly every instance. Outbreaks of plague occur from time to time in the Union of South Africa. In 1941 Gale[4] reported an outbreak of 37 cases in a native reserve: all but one were pneumonic and 36 fatal. The origin of this outbreak was thought to be the springhare (*Pedetes caffer*) or the multi-mammate mouse (*Mastomys coucha*). Davis[5] reported plague to be enzootic in the rodent population over a large area of the Union. The main source of infection for man was the multi-mammate mouse, which occupies the abandoned nests of the gerbilles, these being the main sylvatic reservoirs of the disease. The mice enter human dwellings and form the link between gerbilles and man. More recently *R. rattus* has been the source, and large numbers have died without traceable infection in the field rodents. Kamal[6] has pointed out that plague is endemic in Egyptian towns and villages.

In the Americas the disease exists chiefly as an ever-present potential danger in the form of sylvatic plague. As a cause of death plague is unimportant on the North American continent. Meyer[7] states that only 17 cases have been recognized in the period 1930-40, but the disease is enzootic in the rodent population over at least 12 western States and at least one Province in Canada. In 1941 infected fleas were found for the first time on ground-squirrels in North Dakota. This is the furthest east that the infection has been found in wild rodents or their ectoparasites and was only 6 miles south of the Canadian border. There is evidence that distribution of the infection is widening and nearing the rat-infested cities and towns of the Mississippi valley. It is also possible that the infection may again invade the Pacific coast cities and military encampments. The list of wild rodents that harbour infection is too long to enumerate and is included in Meyer's excellent lecture on the ecology of plague.[7] The movement of large numbers of military personnel into areas where plague is known to exist has created greater interest in the suppression of this infection. What is wanted is something that will kill the flea as well as the rodent. Methyl bromide and carbon disulphide appear to be the chemicals of choice.[8] The former is the most efficient and is non-explosive, but it is expensive and more toxic for man. For merely maintaining a ground-squirrel-free belt carbon disulphide is efficient and reasonably economical, but some fleas may escape destruction. Fortunately the other factors which seem necessary to initiate human infection seldom occur in the U.S.A.

In the Far East, Madagascar, East and South Africa, and elsewhere a number of prophylactic vaccines have been tried. The most satisfactory appear to be those made from an avirulent strain first discovered and used by Otten in Java.[9] In large-scale usage this type of vaccine has apparently reduced the mortality rate by almost 20%. Many drugs have been tried in treatment in the past, but with little effect. However, the sulphonamides have improved the prognosis. Plum[3] in Nairobi found that sulphapyridine in large and frequent doses given within two days of the onset of illness caused a fall in the mortality rate of bubonic cases. Wagle and his colleagues,[10] on the other hand, found immune serum as effective as sulphapyridine or sulphathiazole. As in many other bacterial infections, these drugs, if used early enough in large doses, can reduce to as little as 12% in bubonic plague a mortality rate which ranges between 50 and 100% in different epidemics (1,541 deaths in 1,558 unvaccinated cases reported in Java in 1939). A full review of the chemotherapy of plague was given in an annotation about 18 months ago.[11]

REGIONAL ANAESTHESIA

Even if the local anaesthetic properties of cocaine had been discovered before the general anaesthetic properties of ether, one may assume that unconsciousness during surgical operations would have been welcomed for its own sake. Anaesthesia had become widespread long before the mortality of operations was being lowered by antiseptics and surgical cleanliness. The public, however, still associated surgical operations with pain and the likelihood of death, with at best a prolonged convalescence. It is little wonder, then, that to-day, barely two generations later, the fear of operating theatres is so prevalent, and patients so often spontaneously ask for sleep when the question of regional anaesthesia is raised. British anaesthetists have subconsciously understood their patients in this matter, and have rarely been guilty of forcing an unwilling patient to remain awake. This was a common sight in Continental operating theatres, for, although the surgeons abroad developed the regional anaesthetic technique to a high degree, they ignored the minds of their patients. Successful regional anaesthesia must wed these two aspects. The public fear of the operating room and everything associated with it must be gradually eliminated by education and propaganda. Anaesthetists must gain anatomical knowledge and technical skill, while those whose hands cannot be gentle and whose tongues must wag while they work should be discouraged from surgery under regional anaesthesia. At the moment, when the patient desires to be asleep, regional anaesthesia should be combined with light general anaesthesia, and it will still be of the utmost value in providing muscular relaxation that could have been produced only by the deepest of general anaesthesia, and in preventing stimuli from the operation area reaching the cortex.

In a comparison of regional with general anaesthesia the local anaesthetic agent must not be overlooked as a source of systemic poisoning. The last fifty years have seen a constant search for a local anaesthetic drug which, while giving effective anaesthesia, is relatively non-toxic. Procaine (novocain) holds the field to-day, but active research is needed even in connexion with this, because large amounts of the order of 2 grammes and more are often being used, and we have little knowledge concerning the relative rates of its absorption and excretion and the relation of these to the concentration and volume of the drug solution used. In the search for drugs having a prolonged action, new additions such as nupercaine, and recently amethocaine (also known as decicain, pantocaine, and anethaine), have been made. Unfortunately, these drugs are several times more toxic even than cocaine; and this is offset only by the extreme dilutions which are effective. No one who contemplates using these very potent drugs should fail to make himself familiar with their pharmacology and toxicology. Deaths have recently occurred in this country and abroad through using amethocaine in too high concentration,[1] [2] while convulsions from both this drug and nupercaine have been reported.[3] It should be borne in mind that their main claim over procaine is the longer operating time they provide, and unless the time factor is important procaine should still be used. Regional anaesthesia holds tremendous promise, both for the relief of pain during surgery and for diagnosis and therapeusis, and it will be to the ultimate benefit of everyone that its study is being taken up by anaesthetists rather than as a minor side-line by surgeons.

A HOUSING INQUIRY

"Questioning," said the great Dr. Johnson, "is not a mode of conversation among gentlemen." Nevertheless, in recent times the questionary has become a dissecting tool of sociology, dividing asunder the joints and marrow of our communal life. Sometimes it has been misused; for example, one of the bodies—not Mass-Observation—in trying to discover people's housing preferences, framed for the unfortunate householder a questionary running to nearly 200 questions, whereas it is the experience of interviewers that attention flags after ten or fifteen. Sometimes biased questions are put. If people are asked whether they would like a refrigerator or a communal laundry or swimming pool the result is to suggest a want rather than to elicit an opinion. Mass-Observation, which is a fact-finding body, has worked out its own technique, endeavouring to collect and collate the points which the people themselves raise, irrespective of outside suggestion. In a recent survey[4] it covers four different groups of housing areas—old towns, garden cities, municipal housing estates, and modern working-class flats. The people give their preferences for suburb or town, house or flat, owned or rented dwelling, and discuss housing arrangements down to the shape of door knobs and gate posts and the virtues or vices of linoleum. In view of the millions of houses which will presently have to be built the inquiry is of real value, though not perhaps as valuable as might be expected. The investigators set out to discover the "dream home" of the people, but the fact is that a very large number of people have no dreams—in other words, no capacity for making mental pictures of what they would like. They take what offers and are only vaguely aware of house satisfactions and frustrations. So far as it can be summarized, the majority want a small suburban house or bungalow, not a flat; it should have modern labour-saving devices, hot and cold laid on to a sink in the scullery, the water-closet in a separate compartment from the bathroom, small windows, built-in cupboards, coal fires for warming, electric points in most rooms, and a garden. *People's Homes* leaves the impression of a long-suffering population of housewives, aware of something better than they have got, but not very hopeful about it in their own lives or clamorous for it. The planners of the future and those who direct housing policy, however, to all of whom this work should be a book of reference, will do well not to take advantage of that fact.

THE PRACTITIONER AS TEACHER

In a paper read to the Health Conference of the New York Academy of Medicine, and now reprinted,[1] Prof. Allen Freeman of the chair of public health at Johns Hopkins University draws attention to the part which, in his view, should be played by private doctors as instructors in the prevention of disease. The private practitioner, he observes, has unique, but hitherto unutilized, opportunities of implanting right ideas on preventive medicine in the minds of the people with whom he comes in contact on his daily round. The principal reason for this failure to seize the occasion is that, to-day in the United States, few even of recent graduates have, as students of medicine, received effective teaching in prevention, while the more senior practitioners, owing to the scarcity of postgraduate courses in the subject, remain as uninformed about it as they were in their student days. What is required is to ensure the better acquaintance of the otherwise duly qualified practitioner with the principles of prevention, in order that, so equipped, he may be more competent to hand on to his patients, and through them to the local public, the essentials of prevention and other aids to health. Medical schools should admit preventive medicine to first-line rank in their curricula, and should establish postgraduate courses in the subject. Such measures will point the young graduate to the preventive field, his absence from which is to be regarded as one of the great tragedies of present-day medicine. But Prof. Freeman is not without hope. Some progress is being made, for, as he tells us, " in many American medical schools the professor of preventive medicine is coming to be regarded as a really respectable member of the faculty."

A BRITISH HOSPITAL FOR STALINGRAD

We print on another page an appeal, signed by the Archbishop of Canterbury, Lord Horder, Sir Gowland Hopkins, and other distinguished men and women, for funds to build a new hospital at Stalingrad. This hospital is intended to be " a permanent expression of the British people's gratitude to the defenders of Stalingrad, who have made such a great contribution to the final victory of the United Nations." This is a project which will, we are confident, receive the warm and whole-hearted support of British doctors, and it would be a happy omen for the success of that professional collaboration between the two countries which it is hoped will develop freely in the coming years if medical men and women in this country were collectively to make a really large financial contribution to the British hospital in Stalingrad. The Joint Committee for Soviet Aid is appealing for £75,000 by June 22. If everyone on the *Medical Register* were to contribute one guinea this aim would almost be achieved without anyone else's assistance. It is obvious that very much more than £75,000 will be needed to complete a hospital which will be a fitting memorial to the defenders of Stalingrad and at the same time a hospital that can play a large part in supplying the medical and surgical needs of the future population of this historic city. Whatever their personal circumstances at the moment are, British doctors, we are sure, will not be behind other sections of the community in giving generously. Cheques should be made payable to the Joint Committee for Soviet Aid, crossed " Stalingrad Hospital Fund," and sent to the Organizing Secretary of the Joint Committee, 171, St. Stephen's House, Westminster, S.W.1.

DESOXYCORTICOSTERONE ACETATE AND NATURAL EXTRACTS OF SUPRARENAL CORTEX

In March the Medical Research Council issued a statement by its Therapeutic Requirements Committee drawing attention to the need for strict economy in the use of desoxycorticosterone acetate and urging practitioners not to prescribe it for any patients except those suffering from Addison's disease. Since the publication of that statement further information regarding the stocks of desoxycorticosterone acetate held by individual firms has become available to the Therapeutic Requirements Committee, and it now appears that the need for conserving supplies in the interests of patients suffering from Addison's disease is not so pressing as was thought. Some of the difficulties experienced in obtaining supplies appear to be due to patent rights and the use of branded names, and it has been suggested that the drug should always be prescribed as desoxycorticosterone acetate. The committee desires to repeat that there is no evidence that this drug is essential for any purpose except the maintenance treatment of Addison's disease, and therefore proposes to continue the classification " B " for it. Natural extracts of suprarenal cortex are indispensable in the treatment of Addison's disease, particularly in the acuter phases, and they probably have a wider field of usefulness than desoxycorticosterone acetate. Adequate supplies of natural extracts of suprarenal cortex are available from glands collected in this country, and the committee therefore proposes to continue to classify them " A." Practitioners who have difficulty in obtaining any of these drugs should communicate with the Director of Medical Supplies, Ministry of Supply, Portland House, Tothill Street, S.W.1.

SURGICAL MISSION TO RUSSIA

At the close of the Hunterian Oration before the Royal College of Surgeons of England on May 26, the President, Sir Alfred Webb-Johnson, admitted two new Honorary Fellows: Col. Elliott C. Cutler, Moseley Professor of Surgery at Harvard University and Chief Surgical Consultant to the United States Army; and Dr. W. G. Penfield, Professor of Neurology and Neurosurgery at McGill University, Montreal. These two surgeons, with Col. Loyal Davis of the U.S. Army, will be taking part in the forthcoming Anglo-American Surgical Mission to Russia. The British section, which is proceeding under the joint auspices of the British Council and the Medical Research Council, will consist of Surg. Rear-Adml. G. Gordon-Taylor, Major-Gen. D. C. Monro, Professor of Military Surgery at the R.A.M. College, Millbank, Mr. E. Rock Carling, and Mr. R. Watson-Jones. The aims of the Mission are to study the results of war surgery in Russia and to explore the possibility of extending medical relationships between the two countries. During the visit to the U.S.S.R. Surg. Rear-Adml. Gordon-Taylor, the senior Vice-President of the Royal College of Surgeons, will admit to the Honorary Fellowship two Russian surgeons: Dr. Nicolai N. Burdenko, Director of the Operative Surgery Institute, Moscow University, and Surgeon-in-Chief to the Red Army; and Dr. Sergei S. Yudin of the Sklifassovski Hospital for Traumatic Diseases, Moscow. The work of the Sklifassovski Hospital was described in an article in this *Journal* eight years ago (1935, **2**, 1118) by Mr. George Sacks, who also gave an account of the work then being done by Prof. Burdenko at the Neurosurgical Hospital.

INTERDEPARTMENTAL COMMITTEE ON MEDICAL SCHOOLS

MEMORANDUM OF EVIDENCE BY THE B.M.A.

The British Medical Association has been invited to submit evidence to the Interdepartmental Committee on Medical Schools and to include therein its views on the following topics:

(1) The desirability and method of linking voluntary and local authority hospitals of various types for the purpose of medical education, and in this connexion the selection, appointment, and payment of the medical staff of hospitals so linked.

(2) The extent to which the teachers in the clinical period should be appointed on a salaried basis, whole- or part-time.

(3) The extent to which general practitioners might assist in the training of medical students.

(4) The facilities which are desirable for (i) house appointments for recently qualified graduates, (ii) refresher courses for general practitioners, (iii) postgraduate students specializing in a particular branch of medicine.

(5) The number of general practitioners who may be needed after the war.

The Council appointed a committee, composed of the following members, to prepare the evidence desired:

Sydney Smith, M.D., F.R.C.P.Ed., D.P.H., Edinburgh, *Chairman*, Regius Professor of Forensic Medicine and Dean of Faculty of Medicine, University of Edinburgh.

H. S. Souttar, M.Ch., F.R.C.S., London, Chairman of Council, B.M.A.

Peter Macdonald, M.D., C.M., York, Chairman of Representative Body, B.M.A.

J. W. Bone, M.D., C.M., Luton, Treasurer, B.M.A.

J. A. Charles, M.D., F.R.C.P., D.P.H., Newcastle-upon-Tyne, Medical Officer of Health, City and County of Newcastle-upon-Tyne

Henry Cohen, M.D., F.R.C.P., Liverpool; Professor of Medicine, University of Liverpool.

V Zachary Cope, M.S., F.R.C.S., London, Surgeon, St. Mary's Hospital; Senior Surgeon, Bolingbroke Hospital

Anthony Feiling, M.D., F.R.C.P., London, Physician, St. George's Hospital and Royal National Orthopaedic Hospital.

F. Gray, M.B., B.Ch., London, General Practitioner.

R. L. Newell, M.D., F.R.C.S., Manchester, Assistant Surgeon, Manchester Royal Infirmary; Lecturer in Surgery, University of Manchester.

W. J. Pearson, M.D., F.R.C.P., London, Physician i/c Children's Dept., University College Hospital; Physician, Hospital for Sick Children, Great Ormond Street.

R. M. F. Picken, M.B., Ch.B., D.P.H., Cardiff, Mansel Talbot Professor of Preventive Medicine, Welsh National School of Medicine

A. Talbot Rogers, M.B., B.S., Bromley, Kent, General Practitioner

I. R. Clout, London, Representative of British Medical Students' Association.

Although the organization of medical schools and of the facilities for clinical teaching presents problems of its own, the subject should be considered not in isolation but in relation to the whole question of the future of the organization of medical services. It is likely, for instance, that voluntary and local authority hospitals may not continue to function as separate systems in their present form but may both be parts of a co-ordinated regionalized medical service. The problem is not merely one of devising methods of linking the present voluntary and local authority hospitals for the purposes of medical education, but of considering the place of the teaching hospital in the future hospital service and the method of associating other types of hospital and medical institutions with the teaching hospital. The method of recruiting entrants to the profession and the needs of the practitioner of the future, whose conditions of work may differ from those obtaining at present, must also be considered.

Conception of a Medical Teaching Centre

A medical teaching centre should be a centre from which medical education, both undergraduate and postgraduate, and research are organized for an area. It should consist of a university medical school and a teaching hospital or hospitals in close proximity, with organized associations between the parent hospital and other hospitals and medical services in the district. Patients should be drawn from a wide area, and the quality of the treatment given should be of the very highest standard so that it may guide and influence the whole of the hospital service in the region.

If a teaching centre is efficiently to fulfil its important functions it must conform to certain general criteria. These should include the following:

(1) The teaching, wherever given, should be organized as a whole and all the parts at all stages should be co-ordinated.

(2) The teaching hospital or group of hospitals should be adequate in size and should contain an adequate and varied supply of teaching material and adequate facilities for teaching purposes.

(3) Clinical instruction, especially in the earlier stages of the course, should, so far as possible, be concentrated in, or in close proximity to, the parent hospital.

(4) The teaching staff, whether at the parent hospital or at associated institutions, should be suitably qualified, sufficient in numbers, and approved for the purpose.

(5) Medical teachers should have clinical control of the beds utilized for teaching, whether at the parent hospital or at an associated hospital.

(6) Admissions should be selective and closely related to the needs of teaching and research.

(7) In all hospitals, whether voluntary or local authority, which are used for teaching purposes there should be a medical board representative of the medical staff to advise on all matters relating to the use of the hospital for teaching purposes.

(8) Adequate residential accommodation should be available for students.

(9) There should be ample provision for postgraduate study and research.

Organization of Teaching.—While the general organization of the teaching is the function of the faculty or other governing body of the medical school, the detailed arrangements for the teaching of the students throughout the clinical years of the course should be in the hands of a responsible member, preferably whole-time, of the staff of the medical school. He should act as an officer of the medical faculty, and among his responsibilities should be the making of arrangements with other hospitals, including local authority hospitals, in the area for the teaching which for some reason cannot be given in the parent hospital. When the facilities of a local authority hospital are utilized for teaching purposes to supplement the work of the parent hospital, the former should be regarded as an integral part of the teaching scheme and not as a mere adjunct. It is to be hoped that when the regionalization of the hospital services is effected the conditions of admission and of medical staffing will be the same in hospitals of all types and that many of the difficulties at present involved in the use of the local authority hospitals for teaching purposes will consequently disappear. There is no reason why, in an area otherwise suitable to become a teaching centre, a local authority hospital which conforms to the requisite standards in buildings, facilities, staffing, and organization should not become recognized as a parent teaching hospital.

Accommodation.—The teaching hospital, whether it be a single hospital or a group of separate units, should be adequate in size to assure full facilities for teaching in the different branches of medicine and surgery. The bed accommodation should be sufficient to enable each student during his periods of dressership and clerkship to be given four or five beds to supervise. It is suggested that in the case of a medical school with 90 to 100 entrants annually there should be not fewer than 900 to 1,000 beds available in the teaching centre for teaching purposes in all branches. Every effort should be made to provide accommodation to enable students to spend a period in residence as clerks and dressers. The present voluntary hospital accommodation is insufficient to afford this advantage, and the Association suggests that local authority hospitals might be used to provide additional opportunities for resident instruction. Although some instruction is already given in local authority hospitals it usually takes the form of demonstrations which the student attends as a visitor; it would be better if senior students could spend a period in residence there and be given the supervision of beds. They should not, however, be regarded as replacing house-physicians and house-surgeons. All resident students should be provided with accommodation for study purposes.

Concentration of Teaching.—It is desirable that instruction, especially in the earlier stages of the course, should be concentrated so far as possible in close proximity to the medical school and the parent hospital. At present much time is wasted because the places of instruction are scattered. If it should be necessary for teachers and students to travel far from the parent hospital means of transport should be provided.

Supply of Material.—It is important that the student should see as large a variety of types of case as possible. Teaching voluntary hospitals do not always fulfil this criterion, inasmuch as they tend to accumulate an undue proportion of the rarer types of disease. While such types are often suitable as the basis of the teaching of the fundamentals of medicine, the teaching centre should also afford a sufficiency of those types of ordinary disease which are more likely to confront the practitioner in his daily work. The use of the resources of local authority hospitals would help to remedy the present defect. In an ideal arrangement some of all types of cases would be sent to the teaching centres, including tuberculosis and other diseases for the treatment of which the State undertakes responsibility.

Facilities should also be available for the student to receive practical instruction in the recognition of the normal in the child and the adult and of the early manifestations of disease, in minor illness, in industrial illness, in chronic illness, and in the social circumstances underlying disease. As full advantage as possible should be taken of the opportunities for teaching afforded by the out-patient departments.

Teaching Staff

The teaching staff, whether at the parent hospital or at associated institutions, should be suitably qualified, sufficient in numbers, and approved for the purpose. If a local authority hospital is used wholly or partly for teaching, members of its staff employed in teaching should be approved for that purpose. Members of the parent hospital teaching staff who are allocated to teach in a local authority hospital should be appointed to the staff of that hospital.

Selection and Appointment.—All medical teachers should be selected from the widest possible field of candidates. Appointments to university chairs in clinical subjects should be made by the university. All clinical teachers should be appointed on the recommendation of an advisory appointments board, which should contain a substantial proportion of university representatives. A unified system of appointments through such a board to all senior clinical posts, whole-time or part-time, in the hospitals linked for teaching purposes would afford the best means of ensuring that some or all of their holders could be approved as teachers. If such unification cannot be attained the advisory appointments board should also consider applications for approval as teachers from members of staffs of hospitals utilized for teaching in association with the parent hospital. In making appointments to teaching hospitals the paramount consideration should be the candidate's ability to teach, practise, and advance the science and art of medicine.

Types of Appointment.—Clinical teachers may be appointed on a whole-time or a part-time basis. All should receive remuneration for their services as teachers. In each teaching centre there should be three types of whole-time salaried posts:

(1) The first type should offer a purely academic career in medicine and the holder should be primarily engaged in research work. The number of such posts in any one hospital should be very small.

(2) The second type should be that of a professor of a branch of medicine or surgery normally appointed on a whole-time salaried basis. Before appointment he should have obtained ample experience in his branch, both inside and outside hospital. He should devote all his time to his hospital duties, and if he receives fees for consultative work he should return them to his employing authority.

(3) The junior teaching staff, such as registrars and clinical tutors, should hold whole-time salaried posts.

The members of the teaching staff who do not fall into the above-mentioned categories should be employed on a part-time salaried basis with the right to private practice.

Status of Teachers.—It is of fundamental importance that medical teachers should have complete freedom in the control of the beds in their charge and in their methods of teaching and treatment. When beds or wards in a local authority hospital are used for teaching purposes the same principles should apply. The teacher should have full clinical charge of the beds concerned, subject only to the general administrative supervision of the medical superintendent. It is believed that in practice no difficulty would arise provided there is good will on both sides. As is suggested above, it is desirable that a member of the staff of a parent hospital allocated to teach in a local authority hospital should be appointed a member of the staff of that hospital in order to give him a definite status.

General Practitioners.—Complaint is frequently made by general practitioners that they did not receive as students the knowledge that they later found to be essential in their daily practice. It is said, for example, that the teaching given in children's illnesses, nutrition and dietetics, infectious diseases, and psychoneuroses is often quite inadequate. In some schools the student is not given any opportunity of mastering the technique of such surgical procedures as a general practitioner may properly be called upon to undertake. Another complaint is that the newly qualified practitioner entering general practice finds that he has been given no instruction in his ethical relationships with his patients and his colleagues, and in his rights and obligations under the National Health Insurance Acts. The Association suggests that medical education would be assisted if suitable general practitioners were invited to advise on and be associated with the training of the student. Medical faculties or medical school committees might with advantage include one or more general practitioners in their membership. The function of these practitioners would be to advise on the curriculum so far as it related to subjects of particular importance in general practice and to ensure that adequate attention was given to them. A similar representation of general practitioners should also be included in the staff committees of all hospitals associated with the teaching of students. In the actual teaching general practitioners could render valuable help by giving instruction in medical ethics, the National Health Insurance Acts, and medical organization, and, under present conditions, by giving practical advice on the finance and equipment of a general practice.

Teaching Methods

Although it is understood that the Interdepartmental Committee is not considering in any detail the methods of medical teaching and the content of the syllabus, the Association desires to emphasize the need for relating the medical curriculum to the organization and requirements of medical practice. Great changes will probably take place in medical organization and practice, and the future provision for medical education must take account of these changes. They may be expected to include the co-operation of general practitioners in group practice, the establishment of health centres in which general practitioners will combine curative treatment with preventive medicine and health education, the provision of a comprehensive consultant and specialist service, both institutional and domiciliary, the regionalization of hospital services, and the encouragement of medical supervision and research in industry. In many respects the present methods of teaching will not produce practitioners competent to reach the higher standard of practice that will be demanded in the future.

One or two general observations may be offered. Students should be taught the fundamental principles of health and disease rather than the diagnosis and treatment of separate diseases. A thorough knowledge of fundamental principles will produce a more understanding practitioner who will be able readily to absorb the advances in medical knowledge and technique as they occur during his career. Many practitioners at the present time find difficulty in keeping abreast of modern medical progress because they did not acquire a sufficient foundation in their student days.

More attention should be paid in the curriculum to the maintenance of health as distinct from the treatment of disease. The general practitioner working in the health centre should do much of the preventive work which is at present undertaken by public health medical officers—as, for example, immunization and the supervision of child life—and he should also be expected to instruct his patients in the rules of healthy living, the principles of diet, the care of infants, and other similar matters that concern health rather than disease. This function of the future general practitioner should be provided for in the medical curriculum.

The Association is informed that in some medical schools students are still required to spend an undue proportion of time in watching major operations being performed by the teacher. For most students this time could be spent more profitably in acquiring under supervision practical experience in those surgical procedures that are likely to fall to the lot of the general practitioner. There are other instances where the teaching could with advantage be made more practical. For example, when the medical school is near an industrial centre the theoretical teaching in industrial medicine, which is obviously to play an important part in future medical practice, should be supplemented by visits to neighbouring factories.

Resident House Posts after Final Examination

It seems to be now generally recognized that, as the Association recommended in its Report on Medical Education in 1934, every student should be required to spend some time in practice under supervision before he is permitted to embark on independent practice. For the purpose of the present memorandum the Association has considered two different views on the method of achieving this end. One view is expressed in the following paragraph of the Draft Interim Report of the Medical Planning Commission:

> "94. It would be an advantage to both the community and the practitioner if, when the medical student has passed his final examination, he could spend some time in practice under supervision before he embarked in practice on his own account. It is suggested that the student should be registered provisionally when he has passed his final examination and that he should then be required to practise under supervision in some approved hospital or health service. The period of such practice should be one year, at least half of which should be spent in one hospital. At the end of the period, provided that his work satisfied the appropriate authority, he should be allowed to complete his registration."

The other view is that the tenure of a house post should form part of the curriculum before the final examinations are reached. Unless the present curriculum is reorganized this suggestion would entail the lengthening of the course. Some supporters of this view hold that the methods of teaching medicine need to be entirely remodelled. They suggest that the course should still be of five years' duration, and that in the first four years the student should be taught the principles of medicine, while the fifth year should be devoted to the teaching of the application of those principles. During this final year the student should act as a house-physician or house-surgeon under the supervision of a teacher.

The Association is strongly in favour of the principle that students should spend some time in practice under supervision before they begin independent practice. It agrees with the Medical Planning Commission that this period should occur after the final examinations have been passed but before the licence to practise independently is granted. No formal examination should be required at the end of the period of practice under supervision, for the value of the experience might be diminished if the student had the prospect of an examination before him. The period should be essentially one of instruction, but the student should assume some responsibility.

The length of the curriculum before the final examinations should remain the same as at present. The student should then spend one year in practice under supervision and should receive reasonable remuneration for the work he does. Six months of the year should be spent in an approved resident hospital post, and the remaining six months should be spent, as the student elects, either in a further hospital post or in another approved form of practice.

Postgraduate Courses for General Practitioners

One of the gravest disadvantages of present-day general practice is that most practitioners have neither the time nor the opportunity for postgraduate study. The knowledge they once possessed grows rusty, their outlook becomes restricted, and they are unable to keep abreast of new discoveries and new techniques. What opportunities there are for postgraduate work are too few and too centralized, the courses do not always give the practitioner what he most needs, and the instruction is frequently given by teachers who are not experienced in general practice and lack understanding of the general practitioner's outlook and difficulties. Postgraduate study should be a regular and recognized feature of general practice, and adequate and suitable facilities should be provided. It is believed that if suitable local authority hospitals were used in addition to the voluntary centres already providing instruction the demand could quite well be met.

The Association submitted a memorandum in 1934 to the Council of the newly opened British Postgraduate Medical School in which it made suggestions for the type and content of courses for general practitioners. These suggestions were accepted as the basis of the general practitioner courses given at the school, and the courses have proved popular and useful. Broadly speaking, general practitioners desiring postgraduate instruction may be divided into three groups: (1) those who need "refresher" courses to bring their knowledge up to date or to verify their own ideas and conclusions; (2) those who are interested in a particular subject or branch of medicine and who desire a systematic course of study in it; and (3) those who wish to become recognized as specialists in a particular branch of medicine and desire specialist instruction. The present section deals with the first group. It is suggested that when a national scheme of medical service is organized periodical refresher courses of the kind indicated should be made compulsory.

Duration of Courses.—The type of refresher course suggested by the Association in the memorandum mentioned above was a fortnight's intensive course, and this method was also adopted in arranging courses specially for insurance practitioners. This type, which allows the practitioner a short complete break from his daily routine, seems to meet with general favour, but there are some practitioners who would prefer a longer course at less frequent intervals and others who feel that week-end courses or weekly one-day or half-day courses at a neighbouring hospital spread over a period of weeks would better meet their needs. Efforts should be made to satisfy all these varied wants by utilizing both voluntary and local authority hospital resources, but whatever the type of course it should be organized on a systematic basis. For the purpose of those practitioners who desire a longer course—say, three months—opportunities should be available for them to be appointed as clinical assistants in the various hospital departments.

Content of Courses.—The ordinary refresher course should comprise:

(1) A "brushing-up" of the knowledge which all general practitioners should possess. This should include a revision of (*a*) the aetiology, diagnosis, clinical course, and treatment of the illnesses with which the general practitioner is in daily contact; and (*b*) methods for the maintenance of health, including nutrition and dietetics, child health, and ante-natal and post-natal care.

(2) Instruction in recent advances in diagnosis, treatment, and prognosis, with particular emphasis on methods which can be applied by the general practitioner unaided. The practitioner may have become acquainted with those advances through the medical literature, and the refresher course should provide him with systematic instruction and an opportunity of performing for himself new methods under the guidance of a teacher.

(3) Instruction in the recent advances in the diagnosis and treatment of common diseases which cannot be applied by the general practitioner unaided, but a knowledge of which should form part of his equipment. General practitioners in the health centres of the future should be associated with services providing the most modern specialist methods of early diagnosis and treatment, and they should be trained to make the fullest possible use of these facilities.

Teaching Methods.—The method of approach to each subject should be as practical as possible. The practitioner of several years' standing will find instruction of the out-patient type more familiar and easier to grasp than academic lectures. Illustrations by cases, films, pathological specimens, etc., should be freely used. The courses should be specially designed for general practitioners and should be given by teachers who are familiar with the general practitioner's difficulties and can sympathize with his outlook. Some parts of the instruction could with advantage be given by suitably qualified experienced general practitioners.

Arrangements for Attendance.—Sufficient courses at suitable centres should be organized to enable all general practitioners to attend them with reasonable frequency. The organization of the scheme should include arrangements for the provision and payment of locumtenents, the payment of the travelling expenses incurred by the practitioners attending the course, and a subsistence allowance or accommodation and board in or near the hospital at which the instruction is given.

Postgraduate Courses in Special Subjects

The arrangements for postgraduate study in the teaching centre should provide for two main kinds of demand for specialist courses—one for general practitioners who are interested in a particular subject and for the specialist who desires some instruction in a subject outside his own specialty, and the other for the practitioner who desires to qualify as a specialist in a particular branch of medicine or surgery. The courses should be organized from the parent hospital and should utilize the resources both in the parent hospital and in the general and special hospitals, whether voluntary or local authority, in the area

Courses in Single Subjects.—The medical curriculum necessarily provides the student with little more than the minimum amount of knowledge required for the commencement of medical practice. After some practical experience a general practitioner often evinces a special interest in a particular subject and wishes to obtain wider and more precise knowledge of it Opportunities of gaining such knowledge should exist at suitable centres. The object of the provision should be not to create pseudo-specialists or pseudo-consultants but to stimulate interest and broaden the outlook of general practitioners. Courses in psychological medicine, diseases of children, industrial medicine, nutrition and dietetics, and socal medicine are examples likely to prove attractive. If, as is hoped, co-operative practice in health centres gives the general practitioner wider scope and more time for thought it is likely that the demand for courses in particular subjects may increase. Courses in single subjects may also be required by specialists who believe that their usefulness would be increased by knowledge of subjects which are related to but not intimately associated with their own specialties. All courses should be organized on a systematic basis and should be of university standard. They should consist partly of academic lectures and partly of demonstrations and practical instruction, and the content of the instruction should be related to the practical needs of those attending. The teaching should be given by the teaching staff of the medical school, who should be associated with the heads of the clinical units in the various hospitals. The length of the course will vary with requirements. It may take the form of a fortnight's intensive course, or the practitioner may be appointed a clinical assistant in an appropriate hospital department for a period of three or six months. The provision of a reasonable number of clinical assistantships for postgraduate students should be a feature of the organization of a teaching centre.

Courses in Special Branches.—These courses will usually be those terminating in examinations for the various specialist degrees and diplomas, and their content and length will be determined by the appropriate regulations. Ample provision should be made in the teaching centre for the teaching of specialists, and the resources of the area as a whole should be fully utilized. Hospital appointments in the area should include a sufficient number approved by the various examining bodies. In making provision for specialist training the changes that are likely to take place in medical organization and practice should be borne in mind. These may include consultant and specialist services available to the whole population, the basing of all such services on the hospital, and the undertaking of domiciliary work by consultants attached to hospitals. A comprehensive consultant and specialist service would involve a redistribution of practitioners, with the appointment of some to areas where they may be out of close contact with a teaching hospital. Provision should therefore be made for such practitioners to return periodically to a teaching hospital for refresher work and training in the latest developments of the specialty concerned. It is hoped that in the reorganization of medical services a definition of the qualifications required for consultant and specialist status will be established. The Association agrees with the suggestion of the Medical Planning Commission that the qualifications and standards of consultant and specialist status should be considered and determined by a recognized central body of academic character, and that one of the essential qualifications should be that the applicant should hold, or have held, a recognized hospital appointment in the specialty concerned. Provision for these posts should be taken into consideration when the facilities for training for postgraduate degree and diploma examinations are under discussion. The standard of the various diplomas should be kept at a consistently high level by constant revision and adaptation to the latest developments in the specialties. Systematic training should be available for all the specialties. While an excessive multiplicity of diplomas is undesirable, there is room for certain new diplomas—for example, in physical medicine and industrial medicine.

Research

Ample provision and facilities should be available in the teaching centre for the active prosecution of research in all branches of medicine. There should be a central body, analogous to the Medical Research Council, whose function it should be to foster and support clinical research. Arrangements should be made for the dissemination in all areas of the results of research.

The Association regrets that it has not had sufficient time to give full consideration to the question of the organization of research. It therefore merely submits the foregoing general principles.

The Profession in the Future

It is not yet possible to form a clear picture of the kind of medical service which will result from the plans for reconstruction now being made, nor is it known what toll of the profession the war will take, but it seems certain that more practitioners will be needed in the future than in the past. Lack of time for good work has for long been the complaint of the general practitioner. More general practitioners will be needed if they are to give a full unhurried service to all patients, to undertake some of the work at present done by public health and school medical officers, to make more regular routine medical examinations, and to pay due attention to the maintenance of health as well as the treatment of disease. More will also be needed to ensure that every practitioner may attend postgraduate courses at intervals or spend a period in a clinical assistantship if he so desires, and that he may take reasonable holidays.

The provision of a comprehensive consultant and specialist service easily accessible to everyone would involve a considerable redistribution of practitioners in this sphere. Whether this redistribution and the provision of domiciliary consultations would necessitate an increase in the total number of specialist practitioners required cannot be estimated until the results of the survey, which is understood to be in progress are known, but it is probable that more specialists and consultants will be required in the future. With regard to public health medical officers the reorientation of the medical services now contemplated involves the transfer of some of the work now undertaken by these officers to the general practitioners in the health centres. The new service may therefore require fewer public health medical officers than at present, but, on the other hand, progress in environmental health may produce new duties for these officers.

Number of General Practitioners.—The Association has been specifically asked by the Interdepartmental Committee to submit its views on the number of general practitioners who may be needed after the war. The number will depend upon the form of the future medical service and the work that general practitioners will be required to undertake in addition to the duties which have hitherto constituted a general practitioner service. Any estimate can therefore be only very tentative. At present there are in Great Britain (i.e., England, Scotland, and Wales), including those temporarily serving with the Forces, between 21,000 and 22,000 general practitioners. On the assumption that, taking into consideration the duties and opportunities indicated in the penultimate paragraph above, a general practitioner can reasonably be made responsible for 1,500 persons, a population of from 46 to 47 millions would require about 31,000 general practitioners—that is, an increase of nearly 10,000 on the present figure. It may be found, however, after further consideration and investigation, that a general practitioner is able to care for a larger number—say, 1,800. In this case the number of general practitioners required would be about 26,000, an increase of nearly 5,000 on the present figure.

Selection of Medical Students.—While it is important that consideration should be given to the nature and extent of the knowledge required for medical practice and the methods of instruction needed, it is also important to consider the human material from which the future doctors are to be made. One of the reasons for some of the inefficiency which undoubtedly exists in the profession to-day is that any student who has or can acquire the money to pay for maintenance and tuition throughout the course and fulfils the educational requirements for admission to a medical school is eligible for training as a doctor, regardless of his suitability in other respects. The selection exercised by deans of medical schools is not always sufficient to exclude from the profession some men and women who, though able to pass the examinations, have not the aptitude, character, or staying power which are required for the arduous and responsible duties of a medical practitioner. The Association recommends that a recognized arrangement for the selection of medical students should be established, with the object of recruiting to the profession any boy or girl, from whatever section of the community, who shows a natural inclination for medicine and who has the character, health, and intelligence necessary for a successful medical career. The selection should be made by a small committee after consideration of a record of the candidate's previous history, a consultation with the head master or head mistress of the school attended, and a personal interview. Every intending student should pass through the hands of this committee as a condition of admission to a medical school. Financial assistance may be necessary in many cases. Although at present a large number of scholarships in medicine are available, comparatively few of them are sufficient to provide full maintenance and tuition fees throughout the course. Candidates therefore tend to be restricted to the middle or upper middle classes. It is probable that there are promising boys and girls in the lower-income classes who would be attracted to the profession if they could be guaranteed maintenance and tuition fees during the whole period of training. The Association recommends that funds be made available to assist selected candidates who could not otherwise enter the profession.

PROVIDENT SCHEMES

Once more Lord Nuffield has not waited on events, but has taken the long view and approved the inauguration by his Trustees of a Central Provident Association, the avowed object of which is to enable subscribers to provide against those extra expenses in illness which would not be covered by a comprehensive health service scheme. It is held that, when the comprehensive health service envisaged by Sir William Beveridge materializes, there will still be many families who wish to make their own arrangements for private-ward or nursing-home treatment with free choice of consultant or specialist.

The new provident association is constituted on a non-profit-making basis, and its solvency is guaranteed by Lord Nuffield's Fund to the extent of £150,000. Membership is open, without income limit, to anyone under the age of 60 who lives or is employed in any part of England, Wales, Scotland, or Northern Ireland, other than the London area, in which a Hospitals Services Association has already been sponsored by King Edward's Hospital Fund. The benefits will be in the form of grants-in-aid towards the cost of consultant and other specialist services and hospital pay-bed or nursing-home treatment. They do not include contributions towards the fees of general practitioners. For the hospital or nursing-home treatment of a subscriber or his dependants £6 a week will be paid for an aggregate period of six weeks in any one year. Substantial grants will be made towards consultant and other specialist services undertaken through in-patient treatment. An adult member will receive up to £70 for any one operation or illness and a family may claim benefit up to £105 in any one year. The annual contribution for a subscriber without dependants is £2 15s. An adult dependant's contribution is £1 15s. a year, and 10s. is payable for each child under 18. Thus, a man and wife with two children will pay £5 10s. for a maximum benefit of £105 in any one year. There is no limit to the number of dependants included in a family membership.

The Central Provident Association's offices are at 16, King Edward Street, Oxford, but area sections are being organized in centres all over the country, including Edinburgh, Hull, Manchester, Tyneside, Hertfordshire, Surrey, and Lincolnshire. A Nuffield Provident Association is also being formed in Northern Ireland. Removal from one area to another will not affect membership. Although benefits are for the time being restricted to grants-in-aid for in-patient treatment, Lord Nuffield's Trustees hope that when hospitals and the medical profession are less affected by war conditions it may be possible to extend the scheme to out-patient treatment, and to provide full cover for families within certain income groups.

Lord Nuffield has thus done for the Provinces what the King Edward's Hospital Fund is doing for London, to which we referred in the *Supplement* of Feb. 20 (p. 27). It is appropriate here, however, to draw attention to that older provident association, the B.P.A., which for twenty years has been the means whereby people of only moderate incomes could insure against the expenses, often otherwise financially crippling, of a serious illness. The chief difference between the B.P.A. and the Nuffield scheme is that the former contributes towards the fees of the subscriber's own general practitioner—that is, it provides a form of medical insurance, a family-doctor benefit—as well as covering hospital and nursing-home charges, operation fees, and the fees of a consulting physician. There is no income limit in the B.P.A. scheme, and it is open to subscribers resident in any part of the country, including London. Whatever health service may be provided in the future as part of any social security legislation, one thing is more than ever certain, that no member of the middle classes need suffer the financial embarrassment which has too often in the past added to the burden of serious illness.

Correspondence

Planning in the Treatment of Cancer

SIR,—In his paper on "Planning in the Treatment of Cancer" Dr. Frank Ellis (May 8, p. 570) draws attention to the necessity for statistical investigation on the results of different methods of treatment in cancer and indicates the lines on which such investigations should be conducted. He does not, however, refer to the need to have some standard of reference in the shape of tabulations showing the results of present methods of treatment in large numbers of cases classified on a uniform system. A study of such tabulations indicates the directions in which further investigations are required, and enables them to be planned to throw light on definite points.

Since April, 1938, the Clinical Cancer Research Committee of the British Empire Cancer Campaign has been carrying on such a survey. All the hospitals in the County of London, including those of the L.C.C., co-operated in returning particulars of every case of cancer seen, whether treated or not, on standard case-cards, of which 31 were drawn up, each comprising a comprehensive questionary appropriate to a particular region of the body. Over 15,000 cases had been registered when the outbreak of war necessitated the cessation of further recording of new cases. The follow-up of these 15,000 cases has been continued by the hospitals concerned, in spite of difficulties caused by war conditions, and analysis of the records is going on continuously in this office. Reports of progress were published in the 15th to 19th Annual Reports of the British Empire Cancer Campaign in 1938-42 and reviewed in the medical press. At the end of the 5-year period of observation it is hoped to publish the results of the whole survey, after which the organization should be invaluable for investigating special problems. This comprehensive survey, at present limited to the London area, should form a valuable basis for similar schemes to be launched by the authorities throughout the country under the Cancer Act of 1939. The British Empire Cancer Campaign will gladly help with information as to its practical working wherever it is proposed to inaugurate a similar scheme. This should meet the admirable suggestions in Dr. Ellis's article.—We are, etc.,

HORDER, Chairman.
W. L. HARNETT, Medical Secretary,
Clinical Cancer Research Committee
British Empire Cancer Campaign.

11, Grosvenor Crescent,
London, S W 1.

Birth Weights on a Sliding Scale

SIR,—I would beg to call your attention to an extraordinary custom which is very prevalent among midwives but apparently unknown to many obstetricians. Some weeks ago I was informed by a consultant that she had found at a certain large maternity unit that the midwives made a routine deduction of 4 oz. from the birth weight of live babies "to allow for the cord and meconium." The birth weight of stillborn babies was, however, correctly recorded. Further inquiries revealed a disconcerting state of affairs. At five other general hospitals the midwives were found to be manipulating the birth weights without the knowledge of the medical staff and sometimes without the knowledge of the matron. Inquiries made from five well-known voluntary hospital training schools elicited that routine deductions were made at two, at two more nothing was known of such a custom, while at the fifth the matron had never heard of it, and it is certainly not done now, but graduate midwives have informed me that it was taught at this school in past years. Of a group of 104 graduate midwives questioned recently, about one-quarter had carried out the practice either at their training schools or in subsequent appointments.

The deductions are in some instances made on a flat rate varying from 2 oz. to 5 oz. at different hospitals, and sometimes on an intricate sliding scale—e.g., nothing for infants weighing under 5 lb., 3 oz. for those under 6 lb., and 4 oz. for those above 6 lb. At one voluntary hospital the nurses are taught to bathe the infant, put on a binder, weigh, and then deduct 4 oz. before recording the weight. To complicate things still further, at certain hospitals, but not at all, these deductions are made for live births but not for still. Perhaps the most disconcerting feature of the whole matter is that it had not occurred to any midwife out of the many questioned that it was her duty to inform the medical officer of the ward or practitioner in charge of the case of what she was doing. The reasons given by midwives for the practice are various, but the intentions seem very similar. Some say it is to prevent the inevitable fall in the baby's weight from worrying the mother. Others plead ingenuously that it was introduced to defeat an inconvenient hospital rule that babies must regain their birth weight before discharge.

The devastating effect of this custom on statistical comparisons of infants' birth weights needs no stressing. Perhaps some of your readers may care to institute inquiries on their own account with a view to securing a uniform and accurate practice in recording weights.—I am, etc.,

LETITIA FAIRFIELD.

Shortened Puerperium

SIR,—As a doctor and the mother of a five-months-old baby I would like to endorse strongly the letter (May 22, p. 644) on shortened puerperium. The first day after my confinement I started my abdominal muscles working, relaxing and contracting them for some minutes several times daily. On the fifth day I was sitting up and moving round the bed, also doing leg-raising exercises. At the end of a fortnight I felt very fit physically and enjoyed short walks.

What did strike me very forcibly was that the attitude one seems to adopt by instinct when carrying a baby in one's arms is very harmful to correct abdominal muscle tone. The mother tends to lean slightly backward with the back hollowed and the abdomen relaxed. If this were pointed out to mothers more "good figures" would be the result of correcting this tendency.

To feel physically fit is not the only requirement. I consider most strongly that every mother going home with a new baby is in urgent need of some woman who will share her household cares for even a short period to allow her and the baby to "settle-in" at home.—I am, etc.,

Liverpool. ISABEL M. GARDNER.

SIR,—Dr. Denys J. Neal Smith (May 22, p. 644) proposes to solve the problem of the shortage of maternity beds by sending mothers home with their babies after an even shorter rest than now permitted. I only wish that he (and I) could experience parturition; we might then agree that the normal, but considerable, processes of involution and repair following childbirth and the management of our newborn offspring, about which we, as newly delivered mothers, have little or no practical experience, well merit three weeks' rest, with experienced guidance and help and freedom from all domestic worries and responsibilities.

He admits that the torn perineum, which he has skilfully repaired, necessitates a longer stay in bed than he would otherwise advise, but refuses to believe that unseen and more important muscles and ligaments need time to heal and undergo repair. Agreed there is no need to postulate a new theory for the pelvic organs; they obey the laws of pathology as do the rest of the body; after unaccustomed exercise they need rest.

Dr. Neal Smith's theory might work well in practice if the newly delivered mother could be sent home with adequate help, free from all domestic cares, so that she could take gradually increasing exercise, commencing by walking on all fours, so that her pelvic floor was not strained. He states that he is certain from his experience that prolapse is more likely to occur in the woman who stays in bed a fortnight than in the woman who stays only a week. Has he yet to meet the mother who, with a baby a month old, has stress incontinence with a feeling of prolapse, and in whom these symptoms slowly but surely disappear? In which class of patient do these symptoms and permanent prolapse prevail—the "pampered" well-to-do or the working-class woman? Let him follow up his cases carefully for another ten years and then inform us which way his experience leads.

Like Dr. Neal Smith I have no concern with the financial arrangements of private maternity homes, but in the interest of the delivered mother my experience suggests that not only should we condone the outcry about the shortage of maternity beds but that we should add to it with all our power.—I am, etc.,

Oxford. J. D. FLEW.

The M'Naghten Rules

SIR,—However dangerous the amateur doctor may be on occasion, amateurism in legal practice may be fraught with considerably greater danger, since there is lacking—as I suppose—the homologue in that profession of the *vis medicatrix naturae* to triumph over both wrong diagnosis and treatment. Yet so clear is the exposition in your leading article of May 15 of the "M'Naghten rules" that I feel emboldened to offer a few observations on a subject which might at any time be of personal consequence to any member of our profession.

In referring to "the defect of the M'Naghten rules" you imply that advance in our knowledge of human psychology during the hundred years subsequent to their institution and continued acceptance should lead to an alteration which would be acceptable to the majority of the legal profession. This advance is represented by the doctrine of irresistible impulse, and the application of the encephalograph.

From the viewpoint of the average man, without special regard to the legal or psychopathological aspects of the problem, it seems peculiar that the law, which has properly set a high value on human life, simultaneously invests the criminal with protective laws of evidence from which an almost ridiculously exaggerated view of the value of a murderer's life can be inferred. But be that as it may, it would seem that the present (M'Naghten) rules are not too strict, for they act as very reasonable safeguards: on the one hand in preserving the principles of criminal responsibility by placing on the defence the onus of proving their true application; and on the other hand in ensuring that no truly insane person shall suffer the death sentence. The desire to save a client from a death sentence is plainly the object of those entrusted with his defence, and acceptance of the plea of "irresistible impulse" achieves this object. But excluding cases of poisoning and the rare occasions when murder is carried out on a coldly calculated plan, we can visualize an irresistible impulse (albeit effective for only a few seconds before the actual perpetration of the crime) in all cases of murder. Furthermore, one is entitled to ask if the M'Naghten rules are applied to any other type of crime than murder. Logically the same pleas might be extended in regard to a minor crime, although I can quite understand the hesitancy of an advocate who recognized that acceptance would lead to detention in a criminal lunatic asylum—a result perhaps worse than an unqualified conviction.

The encephalograph is, I take it, still in the experimental stage, and only the result of tests upon a very large number of apparently normal persons will prove its ability to be so selective as to indicate abnormalities solely attributable to a person of homicidal tendencies.—I am, etc.,

London, W.1. ADOLPHE ABRAHAMS.

Advice on Sterility

SIR,—Lord Horder's letter on advice on sterility (May 22, p. 644) annoyed me very much. It is another example of the way that the general practitioner and family doctor is being shouldered out of the responsibility of his job and made to give way so that the public who used to, and still should, in the first place apply to him for advice are gradually being trained no longer to avail themselves of his sympathetic interest but to become cases in a clinic complete with number. To my mind it is far better for young married people who have often known, and been attended by, their doctor since they were born, and who have the greatest confidence in him, in the first place to consult him and seek his advice about their inability to have a child. Modern consultants seem to have no idea of the necessity for maintaining the personal element from which springs the confidence that is so necessary in illness.

Lord Horder "believes that there is a great opportunity to reach a certain type of patient who is not likely to present herself at a hospital out-patient department complaining of sterility." Has Lord Horder never heard of the general practitioner to whom practically all of the patients come in their difficulty? He must have done, and so is adding his quota to the gradual death of family practice and the gradual introduction of the inhuman and unsympathetic State Medical Service, unwanted by both doctors and patients.

In the last few years many women have come to me to ask my advice upon how to become pregnant after, in some cases, even a few months of sterility. I send them to our local gynaecologist, who carries out all the necessary investigations on the woman and often on her husband, and he instructs me in the details of the treatment, and I let him have reports on progress from time to time. These patients, some of whom I may have known for years, are by that method far more satisfied than if they became numbers at a clinic with no one behind them whom they know, like, and respect. They realize they are being treated by their own doctor instructed by the specialist, and it would astonish Lord Horder to see the pleasure with which they come to me and proudly say how pleased they are to find all our efforts have been successful. When their time comes they have the greater faith that I will "pull them through," and, as faith works wonders, they do well. I have within the last three months had three such cases to deal with, and their confinements have been singularly placid and successful, largely due to their belief in me.—I am, etc.,

Bracknell, Berks. R. H. P. HICK.

Withdrawal of Blood for Transfusion

SIR,—A safety valve for an electric suction pump used for obtaining blood for transfusion was described by Dr. E. M. Watson (March 13, p. 321). No criticism is here intended or implied in regard to this particular apparatus.

We would, in the light of our experience in the bleeding of large numbers of donors, question the necessity for suction in the withdrawal of blood. We consider that suction is neither necessary nor desirable. Some thousands of donors are regularly bled by the gravity method in the regions under our charge. The method is easy and simple. The introduction of the principle of suction merely complicates unnecessarily what is, and should be, an extremely simple procedure. That technique should be simple and safe is a principle which requires no emphasis, and the method should at all times be reliable. It should be equally applicable in great and small hospitals alike, and must not fail under stress of special emergency conditions.

It may be argued that suction accelerates blood withdrawal; but there is evidence that this is not always in the best interests of the donor. The smooth flow of blood can on occasion be interrupted by suction of the wall of the vein into the needle. Nothing is to be gained by speeding up the rate of blood withdrawal or by complicating technique. It is not uncommon for a single medical officer to bleed one to two hundred donors in a day with the aid of a few nurses and working perhaps in a village hall. Suction is never necessary whether a 24/10 or 19/10 needle be used. There is the possibility that blood taken off by vacuum may be haemolysed or otherwise spoiled, especially as it offers greater opportunities for contamination. Since there seems to be no special advantage to be derived from the use of suction, which introduces other possible dangers, blood withdrawal by the gravity method appears to us to be the ideal method, and therefore, in our opinion, the method of choice. It has stood very extensive trial, is completely reliable and completely safe.—We are, etc.,

Crush Injury and Anoxia

SIR,—In his letter (Nov. 14, 1942, p. 588) Dr. J. A. Barclay, while agreeing that the crush syndrome and blackwater fever are similar conditions (as emphasized by Dible, *Journal*, 1941, **1**, 904), apparently rejects the suggestion that the renal changes in blackwater fever are due to anoxia, on the ground that Ross was unable to find an increase in blood lactic acid in malaria. In Manson's *Tropical Diseases*, 10th edition, page 89, Manson-Bahr states that in blackwater fever "with the replacement of active functioning red blood cells (by transfusion) urinary secretion is rapidly re-established." This being so, it would appear certain, for the reasons given in my previous letters (Oct. 24, 1942, p. 495, and July 26, 1941, p. 139), that anoxia is the cause of the anuria in blackwater fever.

The conclusion arrived at in the same letters—that the anuria and renal changes met with in crush injury are due to anoxia following traumatic shock—receives additional support from your leading article "Experimental Shock and the Crush Syndrome" (Aug. 22, 1942, p. 222), in which you state that severity of shock and severity of renal damage in crush injury seem to run parallel, and to depend on the extent of the injury. I would suggest that the biochemical changes found in crush injury are the result of (1) trauma, (2) the generalized damage (renal, etc.) caused by anoxia.—I am, etc.,

Sydney J. WALKER TOMB.

Oedema of Extremities at Sea

SIR,—I shall be glad if you can find space in the *British Medical Journal* for the following expression of my own experience and views on a matter which has caused anxiety in the minds of R.A.M.C. officers in charge of transports recently—namely, the occurrence of oedema of the feet and ankles in fit men during a voyage.

I have considerable experience of life at sea in a large variety of types of ship, both fighting ships (as I was a temporary surgeon R.N. 1914-19) and merchant ships, large and small. In fighting ships I do not remember any trouble with oedema, but in pleasure voyages in liners I have often experienced oedema of my own feet and ankles at times when I have been quite fit otherwise. I believe this is induced by reclining in deck chairs or on the deck itself for want of anything better to do. The natural position on the upper deck is to face out towards the sea, and owing to the slant of the deck towards the side and the roll of the ship, there is a form of centrifugal action set up which I believe is the cause of the oedema. I have found that exercise (e.g., deck sports) tends to get rid of the oedema, and I agree with the suggestion in the R.A.M.C. publication on this subject that wearing rubber shoes tends to make oedema more likely.—I am, etc.,

HAROLD E. THORN.

Bovine Tuberculosis in South Africa

SIR,—In this country there is evidence that some factor in addition to the presence of bovine bacilli in milk has a determining influence on the number of human infections. One is led to consider such a possibility in view of the following:

The human disease of bovine origin is exceedingly uncommon here. There have only been three proved cases in the last ten years, as the outcome of a diligent search over that period. This search was sponsored by the Government, and a great deal of bacteriological work was carried out. Moreover, surgeons will tell you that the typical non-pulmonary lesions of this disease in humans are not commonly seen by them.

Now, what of the disease in our dairy herds? Ten years ago when a campaign was started for slaughtering all reactors in the Durban area over 30% of reactors was found in all herds. That campaign was soon dropped, however. Since then the bacteriological testing of milk in the Johannesburg area has shown that 2.5% of cows are excreting bacilli. This, admittedly, is not very high, but can it be considered low enough to account for the rarity of human cases? Either we are making a mistake somewhere or there is another factor in this disease which is eluding us, for there is no doubt that we are, one might say, getting the Toronto results without pasteurization or heat treatment of any kind.

Milk here is consumed by the vast majority of people in the raw state, and very little of it is T.T., although the pasteurized article is being slowly adopted by the more enlightened elements of the European population. Moreover, the standard of general cleanliness of our milk is not very high, because our native milkers make it almost impossible for us to have it otherwise. The community is probably, therefore, getting a large number of other infections handed to it, and for that reason enforced wholesale pasteurization is almost certain to come here after the war. I only hope that our milk will not become too dirty to pasteurize properly through attention being drawn away from the necessity for clean production and replaced by faith in a machine.

However, the point of this letter is to stress the apparent peculiarity of our bovine disease position. Dr. A. H. Macdonald will probably say that we are maintained immune through constantly consuming small numbers of bacilli. E. J. Pullinger of the municipal abattoir, Johannesburg, thinks that the explanation can be found in that relatively few infected cows become excretors of bacilli in this country, although he says that tuberculosis among them is widespread. Yet I cannot help feeling that if 2.5% of our dairy cows are excreting the organisms there ought to be many more human cases; or is there something in this subthreshold oral vaccine business after all? However, in a country like this, where we have so much enteric and dysentery, the case for pasteurization is overwhelming. We have just had a large proved milk-borne epidemic of typhoid in this city. A native milker of a big dairy was found, through the agency of the Vi test, to be heavily excreting the bacilli in both urine and stools.—I am, etc.,

Durban. BASIL F. SAMPSON.

Atropine Glaucoma

SIR,—Dr. J. E. Martin's opening sentence (May 22, p. 631) runs: "This tragic condition continues to blind many eyes." Surely this is nonsense. Never having seen a patient so blinded, I consulted a senior colleague, who with difficulty recalled one case, and even that was open to doubt.

It is right to be wary of instilling atropine into the eyes of elderly patients who have a shallow anterior chamber, but if this should be necessary, the harmful effects have been rather overstated in the past. It has even been said, with some truth, that if atropine should send a patient into acute glaucoma, that patient had a chronic glaucoma already, which is now diagnosed for the first time in circumstances that allow of skilled attention, instead of being overtaken by the acute condition perhaps at night and far from help. There are several eye diseases which are "tragic" and "blinding," but surely atropine glaucoma is not one of them.—I am, etc.,

London, W.1 SEYMOUR PHILPS.

Health Units in the Colonies

SIR,—In your editorial on health units for the West Indies (May 22, p. 639) you remark that the health unit is a new idea for the Colonies. Health units have, in fact, been in operation in Ceylon since 1926; they were advocated for Mauritius in 1931 and formed there during the following year; health centres on somewhat similar lines were developed in Kenya several years before 1933 and in Uganda in that year; in the Straits Settlements organizations of comparable nature were operating before 1933. Health units have been known for a considerable time in India, the Philippine Islands, and other countries. These units and centres differ in some respects in the various countries, but the main object of all is the improvement of rural health; they have unequivocally proved their value. I feel that it would be unfair to the many officers of the Colonial Medical Service who have initiated and expanded these units, and to the native staffs who have carried out so much of the work, if your editorial were allowed to pass uncorrected.—I am, etc.,

CHARLES WILCOCKS,
Acting Director, Bureau of Hygiene and Tropical Diseases.

Chemical Luminescence Test for Blood

SIR,—In reply to the letter of Dr. S. R. Naidu and Mr. N. Pitchandi (May 8, p. 583) the chemical luminescence test for blood is certainly not specific, as it is given by potassium permanganate and many other common oxidizing agents. However, we have found it very useful in testing for occult blood in stools when false positives due to contamination are extremely unlikely. Here the test has the great advantage of simplicity, and in wartime saves the use of guaiacum, benzidine, and ether. The luminescence is so strong that absolute darkness is hardly required. We have found it to be as reliable as the more orthodox tests. A short account of the method as applied in this way is in preparation by one of us (J. L. H.) and will be published elsewhere.—We are, etc.,

J. L. HOSKINS.
Coulsdon, Surrey. R. E. REWELL.

London Emergency Bed Service

SIR,—The exigencies of war have probably affected the medical profession more than any other—general practitioners in many cases are doing double duty—and it is more than ever important that measures which save them time and trouble should be brought to their notice. Owing to the great changes in the personnel of the London doctors, a considerable proportion of them are unaware of the facilities provided by the Emergency Bed Service. For their benefit the following brief particulars may be helpful.

The E.B.S. is financed by King Edward's Hospital Fund for London on behalf of the voluntary hospitals, and arranges for the admission to hospital of urgent cases but does not deal with waiting-list cases. It is able to give immediate advice to doctors as to which hospitals are likely to be able to admit their patients, as it keeps a running record of available beds. The doctor decides which of these hospitals he thinks most suitable; the E.B.S. then rings the hospital and books a bed, and when necessary arranges for an ambulance to collect the patient. Thus doctors obtain the admission of their patients to hospitals of their choice by making one telephone call and are saved the possibility of many unnecessary calls to hospitals which have no empty beds. In the five years in which the E.B.S. has been working no suitable case has been refused, some 22,000 having been admitted through the Service.

The Service is open from 9 a.m. to 10 p.m. daily, including Saturdays and Sundays. Telephone numbers are City 2162 and Clerkenwell 6571.—I am, etc.,

H. A. WERNHER,
10, Old Jewry, E.C.2 Chairman.

Independence for Medicine

SIR,—I wish to draw to your notice the following observations upon medical reorganization, as I believe the views expressed must coincide very nearly with those held by the majority of the medical profession. Assumptions based on false premisses may still mislead us in our endeavour to improve on our service to the public.

An independent practitioner, consultant, and auxiliary medical service is essential to the welfare of the people. The private doctor must remain the friend of his patient—his advocate, as he has always been—whether the patient be rich or poor. He must not serve the State first; the individual makes the State. He must be independent in order adequately to represent his patient's interests in relation to those of the community. The State doctor must owe his first duty to the State. Let the two systems flourish in the English way, with mutual advantage and respect.

The present medical service provided by the National Health Insurance Acts should be expanded. So far as is possible, doctors in the State service should be encouraged to have private patients in order to keep them in touch with the needs of the individual. Conversely, doctors in private practice should be given extended opportunity for part-time hospital and State service, so that community needs—such as control of certification, records, economic use of public funds for medicines and appliances—should be correctly observed. Acknowledgment of both principles will bring unity to our profession, and will attract to it the many new entrants it requires.

Health centres are of value in providing facilities for seeing patients who are able to visit the centres, and in bringing doctors together. But they are necessarily of limited value, because two-thirds of a doctor's time is spent in visiting patients in their own homes, and much of this work will remain in the doctor's own hands, even to the point of arranging his rounds and responding to unexpected and urgent calls upon his services.

The plan should be to improve and expand the present medical services. Though it is acknowledged that they are not good enough, nevertheless they are very good. They form a good foundation on which to build. The same principle applies to the voluntary and municipal hospitals. Let the minor defects in each system be remedied gradually. It is pure iconoclasm to contemplate pulling down either edifice simply because the system of illumination varies or is imperfect.—I am, etc.,

London, W.1. G. H. ROSSDALE.

Achieving Reform

SIR,—The discussion concerning the necessity for or advisability of a State Medical Service to provide a "comprehensive" medical service for the whole nation proceeds on its inconclusive course without any practical exposition of what is intended by a "comprehensive" service. We have recently listened to many excellent speakers, who, however, have left us in doubt whether their vision is on a par with their oratory, while the custom of dragging red herrings across the trails of one's opponents continues as of yore. Changes in the organization of the profession are inevitable; let us see to it that they are worthy of our profession.

Two sides of the question have to be considered—the medical and the economic—and, I think, in that order, planning first an ideal service and then deciding how it is to be financed, cutting our coat according to our cloth. I cannot subscribe to the opinion expressed at one of the recent meetings by a distinguished surgeon that all is well with the profession, which only needs to be left alone without Government interference. As an instance of Government failure he mentioned the case of a boy in hospital under his care who required sanatorium treatment and who, after a long waiting period, still occupied a bed much needed for another case because no sanatorium was ready to receive him. I know personally a patient who has been waiting three months for the much-needed treatment of a secondary growth. But is this to be ascribed to Government neglect or to the failure of our profession to impress upon the public the need for more institutions or centres where the necessary treatment could be obtained? Health centres are to provide additional means for diagnosis and treatment, not, *pace* Dr. Charles Hill, to furnish general practitioners with consulting rooms, although, admittedly, the latter object was part of Lord Dawson's scheme.

Much as I respect and honour my brother practitioners, I cannot claim for them that as a body they are very active reformers. The idea of rheumatism clinics spread very slowly after I had in 1921 persuaded the Kensington Division, B.R.C.S., to found one, and I do not recall any medical support in the Press for my advocacy fifteen years ago of more provision for the early diagnosis and treatment of cancer. The much-criticized Mr. Bevin long before he entered Parliament spoke of the great need for more convalescent homes, on which subject the profession has not been very audible.

We must not be satisfied with things as they are; Government assistance will be needed, but that does not necessarily mean that we must have a State Medical Service. That might indeed bring about many needed reforms, but illness is too intimate an affair to be regimented, and better results would probably follow a well-organized development of the present system.—I am, etc.,

London, W 8 HAROLD H. SANGUINETTI.

State Medical Service

SIR,—The correspondence I have received since you published my letter on April 3 indicates how widely spread in the profession is the alarm at the idea of a State Medical Service—an alarm which has been notably increased by the article of the Medical Correspondent of the *Times* and the subsequent leader on "absent doctors" in that journal. In the latter it is stated that there is no reason why the absent doctors should be thought less progressive (an entirely question-begging epithet in the circumstances) than those at home or that the views of the two groups differ. As a comment on that I may quote from a letter sent to me this week by an absent doctor: "Since joining the Services nearly 2½ years ago I have had the opportunity of discussing the future of medicine with Service M.O.s from many different branches of that calling—G P.s (like myself), newly qualified doctors, and so on. Only two have expressed a desire for a State Medical Service. Indeed, as time passes, there is a growing concern as the full implications of State service are more clearly realized."

I sympathize with our representatives faced in conference by politicians practised in the arts of suave diplomacy. As a profession we are under the handicap inherent in a democracy; we lack a complete alternative plan and we are not all of the same mind. We are as anxious, however, for the good health of the community as anyone; indeed, we showed that interest long before the somewhat belated conversion of the politicians. The principle of insurance has been conceded, and we should concentrate on the question of keeping control of the conditions under which we serve the community. But protests against exploitation must continue, and signs are not lacking that these are beginning to have some effect. Lord Dawson's statesmanlike appeal for evolution and not revolution will carry weight. Even the *Times* in its leader of May 17 is less coercive in tone, and appeals to our "tradition of disinterested social service." Yes, but in return we claim the right to justice and proper consideration.—I am, etc.,

London, W 1. W. LANGDON-BROWN.

Specialists and State Service

SIR,—During the past three weeks I have undertaken the duty of circularizing the greater part of the radiologists throughout Great Britain and asked them to answer a number of questions in the form of a questionary, which was drawn up to ascertain the feeling of this group of specialists concerning their future and the part they would be prepared to take in any comprehensive medical service that might be introduced in the future. The analysis of this inquiry is as follows:

The proportion who replied represented approximately 50% of the total. Of those who did not reply some are on active service and did not receive the questionary, others have died, and the remainder have observed a benevolent neutrality. The replies, therefore, may be regarded as representative of radiologists throughout the country.

1 AGAINST a whole-time State Medical Service	85%
2. Those who seek a haven of rest in a whole-time State Medical Service	13%
3. The final neutral residue	2%
4. In favour of a part-time State Medical Service, permitting private practice	84%
Against a part-time State Medical Service	16%
5. For no form of State Medical Service at all	14%
6. Those who prefer to continue their private practices from their own private rooms	57%
Those who prefer to do all their work (including private practice) from a hospital department	43%
7. Those who desire the interests of radiologists watched	100%
8. Those who desire the formation of some representative medical committee to watch their interests	93%

It is clear from these returns that the majority of radiologists in Great Britain support the policy in general as advocated by the B.M.A., but not that as advocated by the Faculty of Radiologists. Recently this body has sent round circulars to hospitals asking for comments. I would refer to the pamphlet issued by this body in Dec., 1942, *Planning of Radiodiagnostic Services for Great Britain*, page 6, under paragraph headed "Terms of Service of Radiologists": "There was also a majority of two to one who held the view that their district would best be served if all *x*-ray diagnostic work, including private work, was concentrated in hospital." The present return to my questionary under No. 6 is a definite contradiction of this statement.

On page 7 the pamphlet proceeds: "Only by the adoption of a planned scheme by a regional authority, armed with powers of persuasion sufficient to ensure its acceptance by the hospitals and commanding funds sufficient to meet added expense, will the *x*-ray diagnostic services be raised to a satisfactory level of efficiency." It sounds like an order from the Nazi headquarters. The pamphlet on *Planning of Radiotherapy for Great Britain* regiments London into six divisions, while the Provinces are to have some ten centres. The paragraph continues: "With such an arrangement it is assumed that the other hospitals in the area would not practise radiotherapy, but would make their arrangements for radiotherapy with the appropriate London centre."

It would therefore appear that the Faculty of Radiologists favours something in the nature of a whole-time State Medical Service which is not favoured by the majority of radiologists in this country. As to the contradictory statements concerning private and hospital practices, it may be that the inquiry on this point was made before many of the radiologists appreciated what a whole-time State Medical Service might mean to them and their futures. They are now beginning to realize what such a change would mean on the basis of terms that have been hinted at during the recent few weeks. Nevertheless, if the Faculty of Radiologists proposes to assume any form of safeguards for radiologists in this country it should announce quite clearly what form of State service it supports, and take immediate steps to correct any erroneous views as to the wishes of radiologists as I have indicated above.

These matters and others were raised by me at a recent meeting of the British Institute of Radiology in London, where I pressed for more active measures to safeguard the interests at this time. As a result of all this we are to have soon a mass meeting of radiologists to appoint a committee to consider this subject. I submit these facts in the hope that they may encourage other branches of specialists and consultants to organize and prepare themselves, and so be in a better position to consider the proposals of the Government when they are issued on a comprehensive medical service for the country, and let us hope we all act in unison.—I am, etc.,

London, W 1. NORMAN P. HENDERSON.

The Government's Proposals

SIR,—Dr. Hill in his comments to the Metropolitan Counties Branch (*Supplement*, May 22) fails to criticize three points.

1. The salaries suggested, which substantially reduce the income of the general practitioner, and in many cases by over 50%. For example, the purchase of a share of a practice bringing in £1,500 gross is common, and the deduction of £150—being 5% interest on the purchase price—and £400 expenses (based on my total personal and surgery expenses, which are 27%), gives a net initial income of £950 instead of the £400 proposed by the Minister, and without an increase for 3 years.

2. Whether a pension is payable. If so, £100 should be deducted from the £950 net to give a pension of £500 at 65 or disablement and £250 for a family allowance in the event of early death (*vide* N.H.I. practitioners' insurance scheme).

3. Whether the compensation for capital is to be full—e.g., 2 years' purchase for a partnership on a three-years average.

I cannot agree with Dr. Hill that we should "stick to fundamentals," as his "fundamentals" exclude the discussion of the proposed reduction of our income, and it seems to me suicidal to omit from the preliminary discussions before the publication of a White Paper the only two points about which most of us agree—namely, that if there is to be a full-time salaried service we should be fully compensated for our capital, and that our income should at any rate not be reduced. I know no Government scheme to reduce the income of any other profession, trade, or occupation.—I am, etc.,

Basingstoke. CHARLES COBB.

SIR,—Although Dr. Charles Hill carried the recent Metropolitan Counties Branch Meeting with a vast and dynamic *tour de force*, there must have been many misgivings in respect of the absence of any collation of professional policy with other vast world movements. There was a great lack of understanding that whereas individuality has to be preserved competition has to be destroyed, both among individuals as among nations, and in industry itself; for it is more and more granted that there must be no divided interest in industry.

In international finance you see it in the Keynes plan for an international clearing house. The adoption of such a plan would compel world trade to fall in with the world forces of co-operation and so destroy that international competition which is the most persistent cause of world war. In industry you see it in the efforts of capital and labour to find a common formula. In foreign affairs every effort is being made to seek a world comradeship expressed, however inadequately, in the Atlantic Charter. Since 1914 the most conspicuous effects that competition has brought into the world have been great wars, vast revolutions, world-wide discontent, terrifying national debts, and floods of unemployment.

But doctors are perhaps too busy doing good even to have noted these things, and their cause. And so they stand aloof, holding their little screaming baby of competition, and imagine they can stand alone in a world that has opened the flood-gates to more human values.—I am, etc.,

London, S E 23 J. C. JONES.

A British Hospital for Stalingrad

SIR,—We all know the importance of the battle for Stalingrad. We all realize that this victory was only made possible by the suffering and heroism of its people. The Joint Committee for Soviet Aid is aiming to raise sufficient funds to build a new hospital at Stalingrad. We earnestly appeal for a nation-wide response to this effort.

This hospital will be a permanent expression of the British people's gratitude to the defenders of Stalingrad, who have made such a great contribution to the final victory of the United Nations.—We are, etc.,

Obituary

HERBERT JOHN SHIRLEY, C.M.G., M.D., F.R.C.S.

The death took place suddenly on May 14 of Herbert John Shirley, consulting anaesthetist to University College Hospital. He was the son of Mr. William Scharlieb, a barrister practising in India, and Dame Mary Scharlieb, who was gynaecologist to the Royal Free Hospital and is still well remembered for her public work in several capacities, especially in the cause of the welfare of women. Their son, H. Johann Scharlieb, was born in 1868, and changed his name by deed poll to Shirley in 1914.

He received his medical training at University College Hospital, London, and qualified in 1894. A little later he took the M.B., B.S. with honours, in 1898 the London M.D., and in 1899 the Fellowship of the Royal College of Surgeons. He served as house-physician and house-surgeon and as gynaecological assistant at University College Hospital, and as clinical assistant at the Hospital for Sick Children in Great Ormond Street. His career as a practising doctor had only lately begun when he volunteered for service in the South African War. As physician and adjutant, Langman's Hospital, in the South African Field Force, he showed those qualities which would, had he chosen to devote himself to it, have carried him to distinction in a military career. He was mentioned in dispatches, and on his return was made C.M.G. Settling again in the practice of medicine in London, he made a special study of anaesthetics, and in collaboration with Sir Edward Sharpey-Schafer produced some original work on the action of chloroform on the heart and blood vessels. During the first world war, although over military age, he enlisted and served with the British Expeditionary Force as lieutenant-colonel, 2/5 Lancashire Fusiliers, and again his name appeared in dispatches. In 1917 he exchanged to the R.A.M.C., became consulting anaesthetist in the Malta Command, and had charge of the military hospital, Manoel, Malta. At the end of the war he was S.M.O. in a motor transport division of the R.A.S.C., and he retained his military rank as brevet colonel commanding Artists' Rifles. He was proud to hold Volunteer and Territorial decorations. His work as consulting anaesthetist to the hospital of his student days was much appreciated, but he did not take any considerable part in medical discussions or publication. He was the author of the article on "Chloroform" in *The Practitioner's Encyclopaedia of Medicine and Surgery*, and in the British Medical Association, to which he was first elected in 1895, he was honorary secretary of the Section of Anaesthetics in 1910 and vice-president of the Section of Pharmacology and Therapeutics, with Anaesthetics, in 1936. He was a Deputy Lieutenant of the County of London.

SIR NILRATAN SIRCAR, M.D., D.C.L., LL.D.

The death in Calcutta of Sir Nilratan Sircar, at the great age for a Bengali of 81, has removed a leading member of the medical profession in India. He was educated at the Calcutta Medical College, and took both the M.A. and the M.D. of the Calcutta University. He soon obtained a large practice, and was for many years a leading Indian consulting physician. He was a member of a well-known Bengali family, another of whom was a leading lawyer and politician, and he was a man of very wide interests. His lot fell at a time when Indians were taking an increasing interest in education, commerce, and politics; in all of these he was in the forefront. He thus became one of the founders and President of the Carmichael Medical College with its own hospital, which was opened during the war of 1914-18 with material financial help from the Government of Bengal, when Lord Carmichael was Governor under the more advanced regime then coming into force in India. This was the first medical college in Bengal which was staffed and controlled entirely by Indians and which educated up to the university standard as opposed to the shorter medical course for a diploma at the Campbell Medical School, whose teaching staff was filled by Indian graduates in the service of the Bengal Government. Sir Nilratan Sircar also became president of the Calcutta Medical Club with Indian members, of a tuberculosis hospital, and of a postgraduate department of science of the Calcutta University, as vice-chancellor of which he also served for a term. Nor did these various medical interests exhaust his energies, for in the movement for the production of Swadeshi goods—that is, country-made ones—he became the proprietor of a national soap factory and a national tannery company. He also took an active interest in politics and served as a member of the Bengal Legislative Council under the reform scheme. He came to England in the 'twenties for a meeting of the British Empire Universities Bureau, when he received the D.C.L. Oxford and the LL.D. Edinburgh. He had previously been knighted in 1918 for his work for medical education. His genial presence will be missed by many of his friends.

W. BREMNER HIGHET, F.R.C.S.

Brigadier GEORGE RIDDOCH, Consulting Neurologist to the Army and Hon. Consultant Adviser, E.M.S., in Peripheral Nerve Injuries, sends the following appreciation:

All who knew William Bremner Highet must miss him and lament his loss. He was a delightful person, quiet, rather shy, but yet definite in his personality and, with a twinkle in his eye to relieve his earnestness. The Peripheral Nerve Injury Centre at Oxford was fortunate in having him as first assistant to Prof. Seddon for the first three years of its existence. His work there, both routine and research, was first-rate, and he held his place well in a brilliant team. Like the others, starting from scratch with little knowledge of the neurology of the peripheral nerves, he applied his keen, painstaking, and critical mind to the variety of problems presented by patients admitted to the centre, with the result that he was becoming one of the leading experts in this subject. It was for this reason that he was chosen to undertake important work in this field for the Army abroad, and on his way misfortune overtook him. It is a sad and wasteful business. He had already accomplished much and was well set to do much more. He will certainly be missed.

The Services

CASUALTIES IN THE MEDICAL SERVICES

Wounded.—Capt. R. H. Berry, R.A.M.C., Capt. G. Dison, R.A.M.C., Capt. J. D. Finnegan, R.A.M.C., Capt. T. Gass, R.A.M.C., Capt. L. G. Harper, R.A.M.C., War Subs. Capt J. W. Logan, R.A.M.C., War Subs. Capt. R. G. MacLeod, R.A.M.C.

Prisoner of War—Major H. M. Alexander, R.A.M.C.

Killed.—Capt. J. G. Cassidy, R.A.M.C., War Subs. Capt. D. W. McCarthy, R.A.M.C.

DEATHS IN THE SERVICES

Major-Gen. JAMES STUART GALLIE, C.B., C.M.G., D.S.O., R.A.M.C. (ret.), died on May 1 at Winfrith, Dorchester, aged 78. He was born at Queenstown and took the L.R.C.P.&S.Ed., the L.R.F.P.S.Glas., and the L.M. in 1894, and also studied at Queen's College, Cork, and in Vienna before entering the Royal Army Medical Corps in 1898. He very soon saw active service in the South African War in the operations for the relief of Ladysmith and throughout the subsequent campaigns in the Orange River State and the Transvaal. He rose to be a director of medical services during the 1914–18 war and did valuable work in superintending the evacuation of many wounded from the casualty clearing stations to the base hospitals in a cheery and indefatigable manner. He was mentioned in dispatches six times, awarded a brevet colonelcy and the D.S.O. for these services, and in 1926 was selected for the medical directorship at Aldershot. In the same year he was made honorary surgeon to the King, in 1928 was made a C.B., and retired in 1930. He married Florence Ostle Crighton of Hove in 1903 and had two sons and two daughters.

Repatriated.—Col. G. P. Kidd, M.C., R.A.M.C., Lieut.-Col. J. T. Lewis, R.A.M.C.

Medical Notes in Parliament

The Consultations with the Government

Sir E. GRAHAM-LITTLE on May 26 asked what answer the Minister of Health had given to a large meeting of medical practitioners held recently to discuss future arrangements for medical practice.

Mr. ERNEST BROWN said he was not sure to what meeting Sir Ernest referred. He thought it well to make clear the situation which Sir Ernest had in mind. Mr. Brown continued: After the announcement by the Government in February last that they accepted in principle Assumption B of the report of Sir William Beveridge and would proceed with the preparation of a comprehensive national health service for the whole population, I began discussions with representatives of the medical profession, voluntary hospitals, and local authorities as to the best ways and means of organizing such a service. These discussions were, by agreement, to be nothing more than confidential and preliminary talks without commitment on either side, and for the medical profession they were conducted by a Representative Committee of medical men and women brought together by the B.M.A. in collaboration with the Royal Colleges. As a basis for discussion I have from time to time put ideas of my own before this committee, and have invited them similarly to let me have their ideas and their full and free criticism of mine. In this way my intention was to arrive at a stage when I could review the whole subject in the light of these discussions, and could then pass from the preliminary stage by publishing a general statement of proposals for open and public discussion in Parliament and elsewhere. Recently this committee came to me with the suggestion that the whole subject should now be referred to a Royal Commission. We considered this suggestion together, however, and it was agreed that the discussions between the committee and myself should continue on the basis—which I for my part had always tried to emphasize in the previous discussions—that the Government was in no way committed to any particular method of organizing the new service, that every kind of proposal which might be put forward on the subject would be equally carefully reviewed, and that, as before, the discussions would commit neither side. The discussions have already been resumed in a very helpful spirit, and I feel sure that before long I shall be able to look at the question as a whole, in the light of all the views expressed to me by this and the other representative groups, and then to publish a statement of the general proposals which I feel should be put before the House and the country for full discussion before any legislation is embarked upon.

Sir E. GRAHAM-LITTLE also tabled a question to the Prime Minister asking him to take steps to appoint a Royal Commission on the future of medical practice. Sir Ernest said a resolution declaring that this was the only effective way to deal with the problem had been forwarded to the Ministry of Health by the medical Representative Committee and subsequently endorsed by a meeting on May 16 which had been attended by about 1,000 doctors. Replying for Mr. Churchill on May 26, Mr. ATTLEE said the question was based on a misapprehension. A suggestion for a Royal Commission had been made to Mr. Brown by the Representative Committee at a recent meeting, but after it had been considered by the Minister and the Committee together it was agreed that the discussions which had previously taken place should be continued.

Replying on May 27 to further questions, Mr. ERNEST BROWN said he had had very fruitful discussions in the preceding few days. He had received definite and constructive proposals from the voluntary hospitals in the previous week. Until the present discussions with all three bodies were concluded he would not consider issuing a White Paper.

Issue of Sulphapyridine to Troops

Sir JOCELYN LUCAS on May 18 asked the Secretary of State for War whether the drug "M & B," or any allied preparation, was supplied to American soldiers in Africa for use if wounded; if there were any figures of the percentage of lives saved thereby; and if British troops were so supplied. Sir JAMES GRIGG: I am informed that drugs of this type were issued to American soldiers in Africa. These drugs are not issued to individual soldiers in the British Army, but medical officers hold the necessary stocks of them. The figures asked for are not available. Replying to a suggestion by Sir Jocelyn Lucas that he should consult with the American authorities and find out what the results were, Sir James said he would certainly collect all the information he could from any source possible. He was, however, *prima facie,* indisposed to distribute these drugs broadcast among the troops without trial. Sir FRANCIS FREMANTLE: Is there not considerable danger in self-medication?

Diphtheria Immunization and Incidence

On May 18 Mr. ALFRED EDWARDS asked the Minister of Health whether children who took diphtheria after the first inoculation were put into the unimmunized class in the records sent to the Ministry by medical officers of health. Mr. BROWN replied that for the purpose of returns regarding immunization of children against diphtheria, local authorities were asked to show in how many of the cases of diphtheria notified in children under 15 the child was known to have completed the course of immunization not less than 12 weeks before the onset of the disease. Children not satisfying these conditions were considered as unimmunized. Returns received from local authorities showed that the number of notifications of diphtheria during 1942 in children under 15 in England and Wales was approximately 28,500, of which about 87% were non-immunized children.

Mr. ERNEST BROWN informed Mr. Viant on the same day that he was aware that only 45 cases of diphtheria were registered in the administrative county of Northampton in 1942. He could not state the percentage of children under and over 5 years of age immunized at the end of 1941. Percentage rates based on the child population of particular localities cannot be precisely calculated during wartime fluctuations of population. He added that the number of children immunized against diphtheria under local authority arrangements in England and Wales up to Dec. 31, 1941, was approximately 547,000 under 5, and 1,818,000 between the ages of 5 and 15. The corresponding figures at June 30, 1942, were 725,000 and 2,114,000; and at Dec. 31, 1942, 1,150,000 and 2,598,000.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Prof. E. W. Riches will deliver the Hunterian Lecture on "Methods and Results of Treatment in Cases of Paralysis of the Bladder following Spinal Injury" on Thursday, June 10, at 4.30 p.m.

No. 19

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 15.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county) (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1943					1942 (Corresponding Week)

† Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* the incidence of infectious diseases fell, except scarlet fever, which rose by 290 cases. There were 2,058 fewer cases of measles, 119 of whooping-cough, 95 of dysentery, and 41 of diphtheria.

The rise in incidence of scarlet fever was general throughout the country, and especially in Yorks West Riding, Staffordshire, and Middlesex, where respectively 81, 40, and 31 more cases were recorded than in the previous week.

Diphtheria was prevalent mainly in the North. The three counties of Yorks West Riding, Lancashire, and Durham had 222 cases, or 37% of the total for the country, but only 75 cases, or 12%, were recorded in the South—i.e., London, the South-Eastern, South-Western, and South Midlands Divisions.

Notifications of measles were only 41% of the total six weeks ago. The greatest declines during the week were: Surrey 223, Warwickshire 147, Gloucestershire 109, Southamptonshire 103, Leicestershire 100, Essex 98. In Gloucestershire notifications have dropped from 1,156 during the week ending March 6 to 98 during the week reviewed.

The only sizeable variations in the trend of whooping-cough were rises in Lancashire 49 and Derbyshire 40, and a drop in Staffordshire 27.

There were 50% fewer cases of dysentery during the week The only area to report a rise was London, where the cases went up from 11 to 22—10 in Bethnal Green and the remaining 12 in ten boroughs. The only other area with many cases was Lancashire, with 23.

In *Scotland* notifications of measles fell by 88 (with 84 fewer cases in Glasgow), and whooping-cough by 82 (50 fewer in Glasgow). An increase in the western area accounted for the 36 more cases of scarlet fever, the largest local rise being in Glasgow, 14.

The Week Ending May 22

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,740, whooping-cough 2,446, diphtheria 619, measles 8,377, acute pneumonia 672, cerebrospinal fever 68, dysentery 146, paratyphoid 4, typhoid 12

Medical News

Medical officers of health are informed in a letter from the Ministry that the sound film on the prevention and treatment of scabies, which was described in these columns on April 10 (p 451), will be available from June 1 for showing on 16 mm. and 35 mm sound projectors. Medical officers who can borrow a projector can obtain a copy of the film from the Central Film Library, Imperial Institute, London, S.W.7 In other cases the help of the Regional Film Officer of the Ministry of Information should be sought in providing projector, operator, screen, etc. A list of regional officers is attached to the Ministry's letter. While the film is not intended for public cinema programmes it is hoped that medical officers will see that it is shown as widely as possible to invited audiences, especially to doctors, nurses, and other health workers likely to come into contact with the disease.

On the afternoon of Thursday, June 10, Dr. S. A. Henry, medical inspector of factories, Ministry of Labour and National Service, will give two lectures on "The Health of the Factory Worker in War-time." The lectures will be given at 2.30 and 3.45 respectively in the School of Medicine, Leeds, and medical practitioners interested are cordially invited to attend.

An interesting series of demonstrations of the work carried out in the gastric and urological units of St. James Hospital, Balham, was arranged by the London County Council for the benefit of medical officers of the Royal Canadian Army Medical Corps and the United States Army Medical Corps on April 29. Senior surgeons of both the Canadian and American Forces were present, and among the visitors was Col. J. C. Kimbrough, the Director of Professional Services to the American Forces. During the morning demonstrations were given by Mr. Norman Tanner, surgeon-specialist, and Mr H. K. Vernon, senior resident surgeon in gastroscopy, on nephro-ureterectomy for ectopic vaginal ureter and cystoscopy and fulguration of villous growth. The afternoon was occupied by demonstrations of partial gastrectomy, slide repair of hernia, injection of oesophageal varices by Mr. Tanner, and cystoscopy, suprapubic lithotomy, and modified Harris's prostatectomy, nephrectomy, and operation for haematocele by Mr. Vernon. Patients and specimens were also seen in one of the wards of the hospital. The visitors expressed their appreciation of the opportunity afforded them of seeing some of the recent developments in gastric surgery in this country and their indebtedness to the L.C.C. for arranging this visit, which is one of a series provided in the Council's medical services for the benefit of Allied and Dominion medical officers.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, London, W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary.

Telephone No.—B.M.A. and *B.M.J.*: EUSTON 2111.

Telegraphic Addresses.—EDITOR, *Aitiology Westcent, London;* SECRETARY, *Medisecra Westcent, London*

B.M.A Scottish Office: 7, Drumsheugh Gardens, Edinburgh

ANY QUESTIONS?

Aspirin and Gastric Haemorrhage

Q.—*Is there any foundation in fact for the statement made that aspirin tends to promote gastric haemorrhage?*

A.—The evidence that aspirin can produce gastric erosions and alimentary haemorrhage in certain individuals has been convincingly presented by Douthwaite (*British Medical Journal,* 1938, **1**, 1143), Douthwaite and Lintott (*Lancet,* 1938, **2**, 1222), and Hurst and Lintott (*Guy's Hosp. Rep.*, 1939, **89**, 173). Reference to the original papers will show that the findings were clinched by gastroscopic observations, and they are generally accepted by gastro-enterologists.

On Hypo- and Hyper-chlorhydria

Q.—*(1) Has vitamin A any effect on hypochlorhydria? (2) Is there any substance that could increase the gastric hydrochloric acid in cases of hypochlorhydria? (3) Is there any truth whatsoever in the statement that smoking increases gastric HCl in cases of deficiency?*

A.—1. Vitamin A has been said to improve both the symptoms and the secretion of hydrochloric acid when administered for two or three weeks in a dosage of 16,000 international units t.d.s to patients with hypochlorhydria. Curiously enough, vitamin A in high dosage is also reputed to relieve gastric ulcers. None of this work is very convincing.

2. A subcutaneous injection of 0.5 to 1.0 mg. of histamine acid phosphate will increase the secretion of free hydrochloric acid in hypochlorhydria, but this is a diagnostic and not a therapeutic measure. It is better to treat the presumptive cause of the hypochlorhydria—iron in hypochromic anaemia; thyroidectomy in hyperthyroidism; dental treatment and gastric lavage in oral sepsis, etc. In many cases of hypochlorhydria there is a strong constitutional factor, and there is no more prospect of getting the acid secretion back than of growing hair on bald heads. In such cases one can if necessary give dilute hydrochloric acid *B.P* 20–60 minims in water at meal-times. But why this bother about the hydrochloric acid? The organism usually gets on quite well without it, and the symptoms of gastritis can rarely be correlated with lack of acid.

3. Excessive smoking causes hyperchlorhydria in normal subjects. Smoking might therefore be expected to increase the secretion of HCl in hypochlorhydria, but only in a dosage likely to cause also loss of appetite and motor disturbances in the gastro-intestinal tract.

Gentian Violet for Threadworms

Q.—*Is the gentian violet oral treatment for threadworms without risk, and if so what are the correct doses for children and adults? Should this treatment be combined with washouts of any kind? Is a preliminary purge necessary?*

A.—The gentian violet treatment of threadworms appears to be without any risk except that it sometimes causes vomiting, presumably because the capsules in which the drug is given have dissolved in the stomach. On the whole I think it best to give the drug after meals, when any irritant effect is minimized. The correct dose is based on the formula: gr. 1/6 for each year of apparent age per day for five days; then five days' rest; and then repeat for five days. Having worked out the dose, divide it into three lots and order it after meals. The drug is put up in gelatin capsules. A convenient method for surgery use is to have capsules containing gr. 1/6 available and work out the quantity as indicated. For adults the maximum dose has not been satisfactorily determined. Probably gr. 2 a day would be suitable. No purge is required and no washouts, but it is well to order some white precipitate ointment for application to the anus at night, and the nails should be carefully cut and cleaned. It is also a good plan to try to make sure that there is no reservoir of infection present in any other member of the household.

Hexobarbitone as Hypnotic

Q.—*Clinically hexobarbitone appears a useful drug in getting people to sleep. Is it more often followed by toxic effects than, say, soluble barbitone? Is the incidence of agranulocytosis high?*

A.—Hexobarbitone given by mouth is an excellent hypnotic when there is no pain. Its action is rapid and its destruction in the body occurs quickly. This makes it safe, and toxic effects are rare when it is administered by the oral route. Agranulocytosis has possibly been produced by various barbiturates in the past, though even this is doubtful. It is less likely to arise from hexobarbitone than the more persistent members of the group. In any case the risk is remote.

Recurrent Haemarthrosis

Q.—*A woman aged 53 suffers from attacks of haemarthrosis of the right knee which occur while she is walking. She has had five attacks in the last seven months, and is quite well in between. She had one attack in the left knee in 1940. I remove about 1½ oz. of blood each time, apply elastoplast, and the joint clears up in a few weeks without the necessity for a second tap. There is nothing to be found wrong with her knee beyond some x-ray evidence of osteoarthritis. She has had varicose veins in both legs below the knee, which have been treated very successfully by injection, but it is clear now that a desirable refinement would be a Trendelenburg operation in each leg, as veins are appearing in the thighs reaching up towards the saphenous opening. Is it possible that her trouble is due to varicosity in the knee-joint? Can any other treatment be suggested? Apart from her knee she is an active and energetic worker; her menopause was 15 years ago.*

A.—Except in very rare instances, varicose dilatation is limited to superficial and unsupported veins; it is therefore very unlikely that this is the cause of the bleeding into the joint. An angioma or other tumour of the synovial membrane is a more possible cause; but rather more probable is a blood dyscrasia. The fact that there has been one attack in the opposite joint supports this view. The coagulation and bleeding times should be investigated, and attention paid to the vitamin content, especially C and P, of the food. If necessary the urinary excretion of vitamin C can be estimated and the result accepted as evidence for or against a deficiency.

Immunity to Virus Infection

Q.—*Is the immunity to a virus fundamentally the same as the immunity to a bacterium?*

A.—Both types of immunity are similar in that they both depend essentially on specific antibodies. Those differences between the two that do exist are dependent on the different modes of life of bacteria and viruses. Parasitic and pathogenic bacteria live in the body fluids of their hosts; viruses are obligate intracellular parasites. Living cells are not permeable to antibodies. This means that, whereas bacteria are readily accessible to the antibodies in the body humours, viruses are protected from them so long as they are intracellularly placed. Only when the infected cells die and break down, discharging their virus content, and the viruses are in transit to new cells, are they exposed to the action of antibodies. We do not yet know how virus antibodies act *in vivo*. Bacterial antibodies so alter the bacteria as to render them an easy prey for the phagocytes; the antibodies and the phagocytes act in conjunction in combating infection. But there is no evidence that the phagocytes play any part in virus immunity. All we know is that, when a virus is sensitized by the appropriate antibody, either it is unable to get inside cells and so cannot multiply, or, if it does get inside, the antibody has so altered it as to render it incapable of multiplication.

LETTERS, NOTES, ETC.

Treatment of Malignant Tertian Malaria

Dr. D. B. Bradshaw (deputy medical officer of health, South Shields) writes: May I thank Dr. Elliot Murray (May 15, p. 613) for his friendly comment on the case of malignant tertian malaria recorded by Dr. Anderson and myself. Let me assure Dr. Murray that we have no intention of advocating the use of quinine as a routine in malignant malaria. We used it in this case at first because we had then no other antimalarial at hand; later we were unwilling to change to some more orthodox scheme of treatment, such as that recommended by Dr. Murray, because the patient's clinical response had been so favourable.

Gastro-duodenal Surgery in the Aged

Dr. G. Whittington (Reigate) writes: In the *Journal* of May 8 (p. 563) appears an article on gastro-duodenal surgery in the aged by Mr. N. C. Tanner, with an account of a successful operation for perforated duodenal ulcer in an old lady of 79. It is stated that, "this being the second oldest case of perforated ulcer on record to recover," I wish to record the case of a lady of 81 who was operated upon by me for a perforated gastric ulcer near the cardiac end, and who made a good recovery. The operation was completed just 2 hours after the occurrence of the perforation, and she is alive to-day at age 86.

THE BRIDGEHEADS OF CHILD HEALTH IN THE FIVE AGES OF CHILDHOOD*

BY

CHARLES McNEIL, M.D., F.R.C.P.Ed., F.R.C.P.Lond.

Professor of Child Life and Health, University of Edinburgh; Paediatrician, Simpson Maternity Pavilion, Royal Infirmary, Edinburgh

At the present time there is much talk, and some planning, on the subject of child health. In a recent debate in the House of Lords on the Beveridge report Lord Dawson (1943) said: "The care of child health should take precedence over almost everything else at the present moment"; and Sir William Beveridge (1942) in his report has declared that "the small families of to-day make it necessary that every living child should receive the best care that can be given to it. The foundations of healthy life must be laid in childhood."

These general statements imply that child health is not only important in itself but affects the health of the population at all ages. Some years ago a statistical study by Kermack, McKendrick, and McKinlay (1934) found a correspondence between the falling infant and general death-rates in Britain and Sweden, and showed that a regular maintained improvement in child health (measured by the infant death rate) was followed later in the same population by a corresponding improvement in the general death rate. The same biological law can be seen in operation in a country like Holland. In 1938 the infant death rate in Holland was the lowest in the world; in the same year in that country the other main categories of vital statistics—maternal deaths, stillbirths, and general deaths—also stood at record low levels. Thus the science of vital statistics confirms the common sense and experience of wise men, doctors, and laymen.

The same truth has been uttered by the poets, ancient and modern. Wordsworth, as one of the moderns, has sung, "The child is father of the man"; while Juvenal has a long priority over Beveridge—"Maxima debetur puero reverentia." All this testimony can be summed up by saying that child health is the main bridgehead of national health.

The Five Ages of Childhood

The period of childhood stretches from birth (and includes it) to puberty. This span of life must be divided into smaller periods or "ages" if we are to bring under medical management the whole term of child life; for these subdivisions of child life differ greatly in their character and therefore in the medical problems they present. Shakespeare in his seven ages of man has allotted two to childhood: "the infant mewling and puking in the nurse's arms," and "the schoolboy, with . . . shining morning face, creeping like snail unwillingly to school." If we are to apply the principles of child health to the period of child life we must give to it, not two, but five ages. Each has its pattern of healthy structure and function, and each its special dangers and disasters; to each belongs a differing set of clinical problems, physiological and pathological, and mental.

The First Age

This is the first month, or neonatal period, and it includes birth. It is short; but it is crowded with dramatic events and is dangerous and deadly, and the measure of our control of it is the stillbirth and neonatal death rates. The total loss of infant life in the first age (stillbirths plus neonatal deaths) greatly exceeds that in the remainder of the first year. In Scotland, since the registration of stillbirths in 1939, the stillbirths and neonatal deaths have been more than twice the deaths in the remainder of the first year; and in England, with lower stillbirths and infant death rates, about the same relation exists. Without detailing the many and interlocked pathological conditions that cause this great mass of infant deaths in the first age, it is enough at this stage to divide them into two groups—those that belong to the obstetrician and that depend upon the care and health of the mother during pregnancy and labour; and those that belong to the paediatrician and that depend upon the care of the baby after birth. Certainly the first age is the most dangerous and difficult bridgehead of child health, and the one which medical practice has had least success in occupying and fortifying. The paediatric problems of the first age are mainly dietetics and protection against infection; and their successful management demands on the part of nurses and doctors detailed knowledge of the new and intricate processes of feeding and digestion, and of a strict technique against infection.

The Second Age

The second age extends from 1 to 6 months; and if the baby enters it with feeding and digestion well established, and under good hygienic management, it is likely to pass through it with little further trouble. It is the age of milk diet; and if that milk is human and taken from the breast of the mother the baby enjoys the double security of an ideal food and of protection from alimentary infection. Rapid physical growth occurs, and the first steps in mental progress are taken—simple muscular control of the body, the use of the eyes, and some awareness of itself and others (I and Thou).

The Third Age

The next age might be called the age of teeth and transition. It extends from about 6 months to beyond 2 years, beginning with the first teeth and ending with the appearance of the last molars. But it includes other important changes which make this period of child life critical and dangerous. The eruption of teeth is accompanied by additions to the simple uniform milk diet, with the possibility of digestive and nutritional disturbance. The great feat of standing and walking is achieved; this means weight-bearing by the bony skeleton, and requires a proper calcification of the bones. It is also the age of the major fatal infections of childhood—gastro-enteritis, pneumonia, tuberculosis, meningitis, and poliomyelitis; of measles, whooping-cough, and diphtheria; while the nutritional disorders, rickets and scurvy, are almost confined to it. Apart from special immunization procedures, protection against these formidable hosts of infection depends mainly upon proper diet and upon a complete system of hygiene in the city, in the street, and in the home; but with powerful aid from sunshine and air.

---

* The substance of an address to the Perth Branch of the British Medical Association.

The third age brings a quickening and a great advance in the intellectual and spiritual life. By means of speech and walking the intellectual horizon is extended. Speech is the sound-register of thought, and is the most powerful instrument for the formation and the exchange of ideas; it is indispensable for the child's understanding of its own self and for its adjustment to other personalities. By walking, the perceiving and registering mind is brought into contact with the wider range of objects beyond the nursery; and whether these be ugly or beautiful, monotonous or varied, the mind seizes them eagerly, enjoys and stores them.

The third age is the passage from infancy to childhood; it is the age of transition. It is a time fraught with physical danger and mental opportunity. In it the two main bridgeheads of child health are still dietetics and infection; and they are weakly held by preventive medicine.

The Fourth Age

The fourth age extends from 2 to 5 years. It is the age of freedom and of play; and this freedom covers the whole life, physical and mental. This freedom is not absolute; but it is much greater in the mental, and especially the imaginative, life of the child than in the physical life. The spontaneous activity of the imagination is now very great, and outruns control by the weak intellectual and critical faculties. It is a time of dreams, "fantasy," and fairy stories; and one which may give a permanent tone and colour to the child's attitude to life and in which the main patterns of conduct and behaviour may be laid down. The imagination is fed and nourished by everything he sees or hears; and his teachers are not only his parents and other official instructors and guardians, but no less his companions and playmates, and the whole world of objects that comes within his ken. He will get a sense either of security or of fear that may remain with him throughout life. Here Wordsworth's great saying is especially true of the mental life—"The child is father of the man"—and the problem of the nervous child and the solitary child begins in a wrong mental environment in the fourth age. The protection of the mental life at this age depends upon similar factors of mental health as in physical life in the first three ages—the *mental food* that is given, and the guards against *mental infection* that are set up. These three years of child life are years of destiny. Although they are the years of freedom and of play, the play is a rehearsal of the battle of life; and the kind of mental armour, weak or strong, that is forged at this time may determine the issue of the real struggle that lies ahead at school and in adolescence.

The physical life of childhood in the fourth age is relatively free of trouble, unless from chronic ailments of respiration and digestion carried over from an earlier age.

The main bridgehead in this age is mental health. The mind in its effort for health has to get control of the body and so acquire decent and comely habits of body. It has also the greater task of getting control of itself, and enters on the long struggle of self-adjustment and of adjustment to others; and this first essay in the discovery of self may determine the final place of the personality in the realm of ideas and in the world of social contacts.

The Fifth Age

This is the age of school: "shades of the prison-house begin to close upon the growing boy." The child is now put under training both of mind and of body: and it may be a rough and sudden change from the age of freedom and play. If the intellectual, the moral, and the physical discipline are harsh and uncongenial the child has always a way of escape, safe or dangerous, into the inner citadel of personality.

On the physical side, the second dentition adds a physical stress to the new mental tensions that have been created. Infection continues to operate, and rheumatic infection is a new danger; while tuberculous infection of the lungs may now reveal itself for the first time, and the banal infections of the upper respiratory tract transmitted from an earlier age may give much trouble. But on the whole the age of school is comparatively free from serious physical disease, with the one important exception of rheumatic heart disease.

In this age of school the training of the intellect has received quite properly the first place in the national system of education; but it is widely recognized that the training of the body in dexterity and posture, and the training in morals and character, deserve a larger place in the educational system than they have had up till now.

In the fifth age the bridgehead of health is education. A complete system of life training must cover all sides of child life—intellectual, moral, and physical—and brings all these parts under a wise and proportioned discipline. This discipline must be strict and thorough, and yet not offend the inner freedom and sanctity of the child's personality.

This is a rapid and sketchy outline of the periods of child life; but these divisions are essential if we are to understand the problem of child health and bring it under better control. This sketch of the five ages of childhood shows the range, complexity, and importance of child health. If Lord Dawson's pronouncement that "the care of child health should take precedence over almost everything else at the present moment" is right, it follows that child health should receive a first priority in the comprehensive medical service now being planned.

Our present standards of child health, measured by our national infant death rates, are unsatisfactory. If we set the infant death rates of our greatest towns in England and Scotland against those of the U.S.A., Australia, and Holland our figures show a still greater disparity (see Chart). In the planning of a better child health service the immediate urgent problem is infant mortality; and the great safeguards against infant death are management of prematurity, infant feeding, and protection against infection. These three clinical problems are included in the term "infant hygiene"; and infant hygiene must obtain a better place in our medical schools if we are to make a more effective attack on the strongholds of infant mortality.

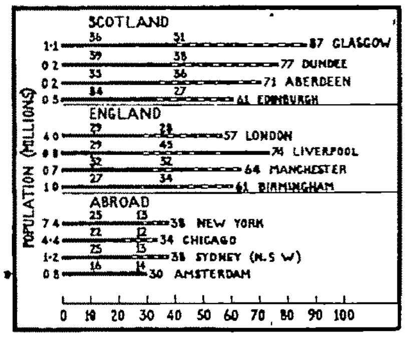

Chart showing infant death rates in 1938 in great towns at home and abroad. The black lines represent death rates for the first month; the black-and-white lines those for the remainder of the first year.

Child Health in the Medical Schools and in Practice

If the standard of child health is to be raised in practice, the training of medical students and nurses must be improved. The range of child health is very wide; in the meantime let us restrict the examination to infant health and infant mortality, and examine the position as regards both education and practice.

Education

In 1932 the General Medical Council strongly condemned the inadequate teaching of "infant hygiene" in medical schools, and recommended "that in the Final Examination there should be a test of the candidate's knowledge of infant hygiene and of disease in children." That recommendation, made 10 years ago, has been more honoured in the breach than in the observance. Among the Scottish universities, Glasgow alone has given the subject a separate place in the Final Examination; and there are signs that some of the English universities will do likewise in the near future. But the fault goes deeper than an inadequate examination test. Very few medical schools are provided with the clinical material of healthy infants and children necessary for the study and teaching of the subject. This clinical material is abundantly available in the child welfare clinics of the local authorities, and especially those attached to teaching maternity hospitals. What is needed is that all paediatric departments in medical schools should include infant and child welfare clinics as a part of their work in treatment, teaching, and study; that separate courses of instruction in child health should be given both to medical students and to pupil health visitors and midwives; and that this instruction should in the first place be mainly directed to the problems of infant health and should include the critical period of the first month.

In the U.S.A. paediatrics has long enjoyed the status of a major subject in the medical curricula. There has been a great fall in infant mortality in the leading American cities in the last 20 years, and it is reasonable to claim that this fall has been influenced by the high standard of paediatric teaching in the American medical schools. In most British medical schools paediatrics is still ranked as a "special" or minor subject. Until this great subject is given its right place in British medical education we cannot expect much improvement in its practice.

Practice

The general practitioner, the hospital practitioner or paediatrician, and the medical officers of the infant welfare and school medical services are at the disposal of mothers for the care and well-being of infants and children. The family doctor handles the problem at its centre, in the home, where the issue of health or disease is decided. He is well placed to make the greatest contribution to infant health, but complains that he is being ousted from it. The paediatrician is fully engaged in the problems of disease in children's hospitals—although a few paediatricians, attached to the welfare clinics of maternity hospitals, are beginning to take part in the health side of the problem. The medical officers of the child welfare clinics are busily engaged there, but form a semi-detached service. They see too little of the health problem in the home and are debarred from the intensive clinical study of the child in hospital. These three services have but slight contact with each other; their liaison is weak, and there is a good deal of recrimination between them. Indeed, each of them is open to attack: for the child welfare doctors and the family doctors have not received a proper training in child health; and the hospital doctors, expert in the problems of disease, have little experience either of home conditions or of the work of child welfare clinics.

It is agreed that this is a most unsatisfactory position; and a good deal of purposeful discussion is going on at the present time to improve it. In the draft interim report of the Medical Planning Commission (1942) plans are outlined to give general practitioners an increasing share in the work of welfare clinics. The British Paediatric Association has also recently brought together in conference paediatricians, general practitioners, child welfare medical officers, and medical officers of health to exchange views and to plan a co-ordinated health service for children. There are great difficulties to be overcome; and before a reorganized child health service can be brought into being there must be full and free discussion of its structure and conditions between all those who will operate it. What is needed is a service in which there will be two kinds of medical personnel—the family doctors carrying out the routine work in the home and the clinic, and the hospital physician advising and directing; while the health visitors will be at the disposal and under the supervision of both. This service cannot work without control; it must have administrative machinery, and must be "under authority." The general solution of this difficult problem of the controlling authority may be found in some local experiment of a co-ordinated child health service—some happy area where there are already friendly relations between the child welfare service, the family doctors, the children's hospitals, and the medical school.

The Fundamental Postulates of Child Health

The medical and nursing services are not the only elements in the complete plan necessary for child health. There are other fundamental postulates which must be provided: general sanitation on a high standard, achieving cleanness and counter-infection in the city, the street, and the air overhead; houses with liberal accommodation and suitable equipment for parents and children; an income-level sufficient to provide food and the other necessaries of life. The central postulate of all is the mother herself; in the last resort the health of the child depends upon the mother's health, her knowledge of her craft, and her devotion. The nurse and the doctor may give her health and knowledge; but the ultimate responsibility for the care of the child rests with the mother, and the centre of the child's life is the home. Day nurseries and nursery-schools cannot take the place of good homes. Minders, be they ever so mindful, cannot take the place of mothers. The family is a human society—the oldest, the smallest yet the greatest, of all human societies. If the family is to be secure and stable it must have all these things that have been mentioned; and it must also be governed by moral and religious laws as well as by the laws of economics, medicine, and hygiene.

Sir William Beveridge has given us his design and plan for national security and health, and has said that "the foundations of healthy life must be laid in childhood." Not unlike his plan, but with a theocratic as well as a democratic foundation, is the Psalmist's dream of a happy and secure society:

> That our sons may grow up as the young plants:
> That our daughters may be as the polished corners of the temple
> That our garners may be full and plenteous with all manner of store: . . .
> That there may be no decay: no leading into captivity, and no complaining in our streets.
> Happy are the people that are in such a case:
> Yea, blessed are the people that have the Lord for their God.
>
> Psalm 144.

SOME ASPECTS OF THE CHEMOTHERAPY OF PNEUMONIA

BY

THOMAS ANDERSON, M.B., Ch.B., F.R.C.P.Ed.

Physician-Superintendent, Knightswood Fever Hospital

That the value of chemotherapy in pneumonia has, in a general way, been proved is a reasonable assumption. The present analysis is put forward in the belief that certain aspects of the results obtained with sulphonamides are not sufficiently or generally appreciated.

The Value of Aetiological Diagnosis

It is well known that in a large proportion of pneumonias the causal organism is a pneumococcus, and that among pneumococcus pneumonias there is considerable variation in the severity of the illness caused by different serological types. It is not so well known that there are differences in the fatality rates when cases receive sulphonamides. In Glasgow, where over a long period of time the commonest type of pneumococcus has been Type II, carrying a high fatality rate, the results of chemotherapy have been less impressive than in the South of England, where the more benign Type I infection is prevalent. My own figures in two relatively large series of cases (Table I) may be cited. The material comprises all cases admitted in which the notified diagnosis of "acute primary pneumonia" was confirmed. The great majority conformed to the lobar type of consolidation. Sulphapyridine was given by mouth; after a preliminary dose of 2 g., treatment was continued with 1 g. four-hourly until the temperature had been normal for a period of two to three days. I have included the results obtained with chemotherapy in

TABLE I

Type	Pre-sulphonamide		Sulphonamide	
	Cases	Deaths	Cases	Deaths
I	172	13 (8%)	64	2 (3%)
II	198	58 (29%)	160	20 (12%)
III	27	4 (15%)	48	15 (31%)
V	—	—	8	1 (12%)
VII	—	—	26	4 (15%)

Type V and Type VII infections, since clinically, in respect of course and severity, they behave very similarly to Type II infections.

I have been the more convinced of the accuracy of the picture to be drawn from these figures by collecting together a number of cases treated in different Glasgow hospitals (Anderson, 1940). In so far as Type I and Type II pneumococcus infections are concerned the result is the same: Type I infections are now usually mild, death resulting from some complicating condition often unconnected with the pneumonic process; whereas Type II infections are more severe and still carry an appreciable fatality rate. The results obtained in Type III infections are more variable; the most important factor here is the age of the person infected. In the older age groups infections with this type are severe and often fatal; but when younger persons are infected the illness produced by Type III pneumococci is milder and the fatality rate low. During 1939-40 and into the beginning of 1941 the Type III cases were predominantly among the older age groups and carried a correspondingly high fatality rate. These figures are, I believe, sufficient justification for stressing the necessity for the continuation of pneumococcus typing, even when the sulphonamides are being used.

The Age of the Patient

In analysing my own figures I have been impressed by the increased importance of age in the results obtained by chemotherapy in pneumonia. In Table II the total figures for Type I, II, and III infections have been divided into two groups, below and above 40 years.

TABLE II—*Results in Respect of Age in Type I, II, and III Pneumococcus Infections*

	40 Years and Under		41 Years and Over	
	Cases	Deaths	Cases	Deaths
Pre-sulphonamide ..	288	40 (14%)	109	35 (32%)
Sulphonamide ..	151	6 (4%)	121	31 (26%)

It is clear that the reduction in fatality is much more impressive under the age of 40 than above it. If Type II infections alone are considered we find that the fatality rate under 40 has fallen from 22 to 4%, whereas in the older age group the fall is from 46 to 25%. Further, an analysis of 69 consecutive deaths from pneumonia of persons over the age of 11 years who received sulphapyridine has shown that no fewer than 56 (81%) of these patients were 41 years of age or over. In Cruickshank's analysis (1942) of cases of pneumonia treated in the Glasgow Fever Hospital from 1918 to 1928, only 40% of the deaths of patients above the age of 11 occurred in those over 45 years old: 68% of my deaths are in this age group.

Effect of Age and Bacteriaemia

Table III shows the results of an analysis of 168 cases examined by blood culture on admission to hospital.

TABLE III.—*Effect of Age and Bacteriaemia on the Outcome of Pneumonia*

Age	Non-bacteriaemic		Bacteriaemic	
	Cases	Deaths	Cases	Deaths
40 years and under	70	2 (3%)	20	3 (15%)
41 years and over ..	56	9 (16%)	28	13 (47%)

(χ^2 = 14 4, P = less than 0 01)

This table contains some important data. The first inference to be drawn from it, of course, is the importance of the presence of bacteriaemia when treatment is begun. But the occurrence of bacteriaemia must be regarded either as a gain for the pneumococcus in its invasive capacity or as a loss for the host in his defensive capacity. There is some reason for believing that the risk of the development of bacteriaemia increases as age advances. May it not be that the relative failure of sulphapyridine in those over the age of 40 with bacteriaemia is due more to the impoverished defences of the host, which have allowed invasion to occur, than to the actual presence of bacteriaemia itself? Our present conception of recovery from acute infections lays much emphasis upon the causative "virus," its different attacking mechanisms, and the immunological changes which it causes in the human host. Just because it is more nebulous and difficult to define we tend to set aside the non-specific or tissue resistance, although we fully appreciate its importance in the host's chances of recovery.

Age, Bacteriaemia, and the Process of Resolution

One further set of figures may be supplied. In my hands, one of the most disturbing features of the case of pneumonia receiving chemotherapy has been the frequency with which convalescence is delayed by what might almost be termed the failure of resolution. Table IV shows the incidence of the condition in a series of unselected cases in respect of the two factors already discussed—namely, age and bacteriaemia.

TABLE IV—*Age, Bacteriaemia, and the Incidence of Delayed Resolution*

	Cases	Cases with Delayed Resolution
Non-bacteriaemic ..	165	21 (13%)
Bacteriaemic	59	15 (26%)
40 years and under .. .	151	17 (11%)
41 years and over	121	27 (22%)

The figures in Table IV show that the incidence of delayed resolution is much higher in those over 40 years and in those with bacteriaemia. Again it seems to me that it is not sufficient merely to say that this complication is occurring in the severer case. In the person over 40 years old and in those with bacteriaemia the "tissue resistance" may be lacking; it might be reasoned that failure to restore the inflamed lung to normal is likely to be due to a failure of tissue resistance. Many of the cases upon which I have performed a necropsy have been found to show upon their tenth or twelfth day a totally hepatized lobe, in which microscopically there is great increase of connective tissue, the fibrin being interwoven by strands of fibrous tissue.

Discussion

It is a natural tendency of the enthusiastic clinician to produce fatality rates as low as he can make them. Where the factors which influence the fatality rate are few little harm can result. But where, as in pneumonia, the factors which influence the fatality rate are many, then it is desirable that he should not undercolour the shadows. These figures have been selected to emphasize the fact that the introduction of the sulphonamide group of drugs has not removed pneumonia from that group of diseases which still requires intensive study. There is evidence that age now assumes an even more important place in prognosis than it did in the pre-serum or pre-sulphonamide days, and that the risk of death, or of a prolonged convalescence, is much greater in those who are past the middle stage of life. A close relation is also shown between outcome and the presence of bacteriaemia when treatment is begun.

These findings suggest that with the introduction of the newer sulphonamides the last word on the treatment of pneumonia has not yet been written. There apparently remains a broad age group in which the disease has a high relative prevalence and in which the individual's chance of recovery, once he is attacked, is less favourable. Nor can it be too greatly emphasized that the loss of a life between the ages of 40 and 60 years constitutes a severe economic blow; for by this time the individual's responsibilities in society and in family life are often greatest. A problem exists, and must be faced, in regard to the more effective treatment of these "bad risk" cases. In the light of our present knowledge three lines of approach may be discussed.

In the first place the combination of chemotherapy with type-specific serums or vaccines must be considered. Comparative trials of combined treatment and of sulphonamides alone have been reported from America (e.g., Plummer *et al.*, 1941). The results do not encourage a belief that added benefit is secured by combined therapy. My own final assessment of a small group of cases does not bear out the promise of the earlier results (Anderson and Cairns, 1940). Serum-and-drug treatment was given to 33 patients with Type II pneumococcus pneumonia. In respect of those over 40 years of age the fatality rate was 25%; delayed resolution was noted in 29%. These findings confirm, on a small scale, the reports of the larger American studies. Vaccines have also been used in two series of Glasgow cases. Dick (personal communication) treated alternately two groups of cases in 1941-2—one with sulphapyridine alone, the other with sulphapyridine plus autogenous vaccines. In respect of fatality rates and incidence of delayed resolution there was no difference between the two groups. My own small experience with type-specific stock vaccines is similarly discouraging. Fleming (1939) has produced strong experimental evidence in support of the use of the combined methods of treatment as compared with either alone. The apparent failure of combined therapy in man must thus be earnestly considered; for since, alone, both achieve a beneficial effect the argument in favour of their combination seems a strong one. It may, of course, be that the fatality rate has been reduced to its lowest level by means of chemotherapy and that those who now die represent a non-resistant population in whom the infection runs a course too rapid for successful intervention. Such a view would be disquieting; but it should in its own way direct attention to the individual, underlying failure which permits lowered resistance to the infection. May it not be, on the other hand, that chemotherapy in man achieves its effect by a host-response different from that of specific serotherapy? The non-specific nature of the action of sulphonamides does not perhaps receive the attention it merits: one drug is successful in infections due to a wide range of micro-organisms. The finding in severe cases of pneumonia—many of which would previously have ended in death—that the return of the consolidated lung to normal is a long slow process suggests that tissue resistance is an essential adjuvant of chemotherapy.

It may finally be asked whether a more intensive course of chemotherapy during the preliminary stage of treatment might not be worthy of trial in these patients over the age of 40. The use of age alone as the criterion might be advocated, since it would seem reasonable that for beneficial effect intensive therapy should be used during the first 24 hours, before the results of blood culture could be known. It would, finally, seem especially desirable when the results of chemotherapy in pneumonia are reported that emphasis be placed upon the analysis of the cases in respect of the type of infecting pneumococcus, the age of the patient, and the presence or absence of bacteriaemia when treatment is begun.

RECEPTION TO PROF. SARKISOV

A largely attended reception was given on May 21 by the Society for Cultural Relations with the U.S.S.R. in honour of Prof. S. A. Sarkisov, representative of the Soviet Red Cross and Red Crescent, director of the Moscow Institute of the Brain, and vice-president of the Scientific Medical Council of the U.S.S.R. The Soviet Ambassador and Mme. Maisky were present, as well as many representatives of the medical services, British and Allied. The company were received by Mr. D. N. Pritt, K.C., and Mrs. Pritt, and a welcome to the guest of honour was spoken by Mr. Aleck Bourne. Prof. Sarkisov, who spoke in Russian, expressed his gratitude for this friendly welcome. Never in the history of mankind, he said, had the scientific and cultural values created by the centuries been exposed to such barbaric destruction as was taking place now. Therefore the growing tendency towards the establishment and widening of the collaboration between cultural, art, and scientific workers in the Soviet Union and the countries friendly to the U.S.S.R. was quite natural. He added that the Soviet intelligentsia, together with the whole Soviet people, were working to help the heroic Red Army against the invaders. As a representative of Soviet medical science he hoped to make scientific medical circles in Great Britain more closely acquainted with the work which Soviet medical men and women were carrying out both at the front and at the rear. He hoped also to become more closely acquainted with the work of the medical institutions of Great Britain in order that in turn he could make the Soviet public acquainted with them. He concluded with expressing his belief that the peoples of the two countries were bound not only in comradeship-in-arms but in an alliance for a long period after the war.

ENTERIC GROUP FEVERS IN PRISONERS OF WAR FROM THE WESTERN DESERT

WITH SPECIAL REFERENCE TO PROPHYLACTIC INOCULATION, JAN., 1941, TO FEB., 1943

BY

J. S. K. BOYD, O.B.E., M.B.

Colonel, late R.A.M.C.; Deputy Director of Pathology, Middle East Forces

Intelligence reports received during the latter part of 1940 indicated that fevers of the enteric group were of common occurrence among Italian troops in Libya. The first Libyan campaign—1940-1—resulted in the capture of unexpectedly large numbers of prisoners, and the available accommodation for their custody was at first stretched to its limit. Until this was adjusted the sanitation of the P.O.W. camps was inevitably of a makeshift type, and the complete lack of sanitary conscience which is common to the Latin races made control a matter of very considerable difficulty. In the circumstances it is surprising that a large-scale outbreak of bowel disease was avoided.

The 1940-1 Outbreak

A small wave of typhoid fever occurred in one of the camps, but by the end of January it was under control. This was achieved by the establishment of rigid sanitary discipline (and in justice it must be stated that the prisoners were quite easy to educate in these matters), by control of the "food-handling" personnel, and by inoculation. As regards inoculation, the supplies of British Army T.A.B. vaccine in the Middle East were inadequate for this unexpected demand, but a quantity of Italian vaccine which was captured along with other medical stores was used as follows. In the Geneifa camps, where the outbreak occurred, all prisoners who could not produce evidence of having been inoculated within two years were given two doses of 0.5 and 1 c.cm. of vaccine at ten days' interval: all others were given 0.5 c.cm. In the other camps, where only isolated cases had occurred, those who could produce evidence of having been inoculated within the previous nine months were not done, otherwise the dosage was similar.

The Summer, 1941, Outbreak

From Table I it will be seen that the incidence remained low until May, towards the end of which month cases of typhoid infection began to occur in considerable numbers. In June a major outbreak was in progress, which reached its peak in July, decreased in August, and came to an end in September. In June three cases of infection with *Bact. paratyphosum* A were identified, and in July there were more cases of this infection than of typhoid. This outbreak persisted through August and declined in September, to disappear in October. It will be noted that many cases were diagnosed on clinical grounds. The majority were treated in one hospital; and the volume of work was such that the laboratory was unable to carry out repeated tests on each case. It may be assumed, however, that the positive results obtained give a reasonable cross-section of the whole.

The cause of the outbreak need not be discussed here. A number of factors were contributory. It is probable that the infection was chiefly fly-borne, and it is of interest that no cases occurred among the staffs of the P.O.W. camps.

The prisoners at this time were, in the main, those captured in the 1940-1 campaign, who were inoculated in January. In the interval reinoculation with Italian vaccine had been carried out as it fell due. Large stocks of this vaccine had become available, and in June, when it was clear that an outbreak was imminent, all prisoners were reinoculated with a further two doses (0.5 c.cm. and 1 c.cm.) of Italian vaccine. This had little obvious effect, and in early August, when adequate supplies of British Army vaccine were received, two-dose inoculation with this preparation was again performed in the affected camps. Following on this, but not necessarily on account of it, the outbreak rapidly waned.

The Nov.-Dec., 1942, Outbreak

Thereafter all newly captured prisoners, on admission to a camp, were inoculated with two doses of Army T.A B as a routine measure, and the incidence ran at a low level, with a slight seasonal rise during the summer months of 1942, until the influx from the El Alamein battle started in Nov., 1942.

Of the 181 cases occurring chiefly among these fresh prisoners, and notified during the four months Nov, 1942, to Feb., 1943, inclusive, details are available regarding 171. In 90 of these the date of onset was 10 days or less after admission to the P.O.W. camp. Some of these were already ill when captured. In the remaining 81 the date of onset bore the following relation to inoculation: 44 cases occurred in 21 days or less after inoculation; 9 cases occurred between 21 and 28 days after inoculation; 9 cases occurred between 29 and 40 days after inoculation; 8 occurred in periods longer than 40 days; 3 were "old" prisoners. While these figures are suggestive, inoculation was only one of many measures adopted to deal with the situation, and cannot be accounted solely responsible for the decline of the outbreak. One fact which is clearly brought out is the prevalence of the disease among enemy troops. The hospital captured at Mersa Matruh contained two wards—one on the Italian side and one on the German side—full of cases of clinically diagnosed enteric fever.

Bacteriophage Types of Strains of Bact. typhosum

The bacteriophage types of those strains of *Bact. typhosum* isolated from prisoners that were sent for investigation are shown in Table II. It will be noted that all three outbreaks were caused by a different type. In Dec., 1940, to Jan., 1941, only Type G was found. In the summer of 1941 Type B4 and Type C were both present. At the same time a large number of cases of paratyphoid A infection occurred. In Nov.-Dec., 1942, the predominant strain was Type A, which had previously not been isolated from prisoners in the Middle East for over a year. Other types were also found, and 41 cases of paratyphoid B infection occurred among Germans.

TABLE II.—*Bacteriophage Types of Bact. typhosum among Prisoners of War: Dec., 1940, to Feb., 1943*

	Dec., 1940 to Jan., 1941	Feb., 1941 to May, 1941	June, 1941 to Sept., 1941	Oct., 1941 to Oct., 1942	Nov., 1942 to Feb., 1943
Type A	—	3	2	—	65
Type B4	—	3	16	1	1
Type C	—	—	64	—	1
Type D2	—	—	—	—	3
Type G	22	10	1	11	3
Imperfect V	—	1	7	4	5
No Vi antigen	1	1	29	1	1

These facts are of interest in that they indicate the widespread nature of enteric group infection among Axis troops.

Enteric Group Fever among British Prisoners in Enemy Hands

In comparison with this, information obtained from Capt. E. T. Gilbert, R.A.M.C., who was captured by the enemy at Gambut on June 23, 1942, and placed in medical and administrative charge of the P.O.W. camp for British and other prisoners at Sidi Hussein, near Benghazi, is of great interest and significance. Capt. Gilbert was unable to give exact figures, as he had no means of keeping written records, but there is no doubt the details are substantially correct. The original strength of the camp was approximately 16,000, the prisoners being British, South Africans, Indians, Free French, Mauritians, and a small number of New Zealanders and Australians. It rose to 24,000, maintained this level for about four weeks, and then fell to approximately 12,000 on Oct. 18, when Capt. Gilbert left the camp It should be noted (see Table I) that this period, June to October, covers the months when the incidence of fevers of the enteric group is likely to be at its maximum.

The sanitation of the camp was primitive in the extreme. For some time the latrines were of the shallow-trench type. Flies abounded, and there was no means of washing (water ration, 1/2 to 1 water-bottle a day per man for all purposes). Almost at once an outbreak of dysentery started, which finally totalled between 11,000 and 12,000 cases in the four-months period. Despite the fact that circumstances appeared equally favourable for an outbreak of enteric group fever, no cases of a suspicious nature were observed during the same period. This cannot be taken to mean that none occurred, but the incidence at most must have been insignificant. This state of affairs was a matter of considerable surprise to Italian medical officers of the Benghazi Military Hospital, to which the more serious cases from the prison camp were admitted. They questioned Capt. Gilbert on the subject, and admitted to him that numbers of cases were occurring among Italian troops in the vicinity.

Comparison of Enteric Group Fevers in British and Axis Troops

Here, then, are two series of events which form a very striking contrast On the one hand the Axis Forces have a constant high endemic level of fevers of the enteric group. Despite inoculation with their own vaccine an epidemic of considerable proportions occurred in the summer of 1941. Supplies of British Army T.A.B. were obtained and administered as the outbreak was on the wane. It ceased abruptly, and the endemic level thereafter remained low even during the "typhoid season" of the summer of 1942. The prisoners captured in El Alamein were heavily infected, but the outbreak was quickly stamped out. On the other hand the Allied prisoners at Benghazi, living in a camp in which sanitation was of a primitive type and conditions were such that a major epidemic of dysentery occurred, and where typhoid was rife among their captors, escaped apparently unscathed.

It is difficult to explain these facts except on the grounds that the Allied troops possessed an immunity which the Axis troops did not. If so, this may have arisen from the use of a more effective vaccine

Comparison of British and Italian T.A.B. Vaccine

Two types of Italian vaccine were captured. One, of which only small quantities were obtained, bore the honoured name of Castellani. The other was a T.A.B. and tetanus-toxoid mixture (T A.B Te.), manufactured by the Istituto Sero-Terapeutico Nazionale, Naples. These vaccines were tested in parallel with British T.A.B. vaccine by mouse-protection test, with the following results. The figures indicate survivors after 30 hours.

Test Dose	Control	British T.A.B.	T.A.B. Castellani	T.A.B.Te.
2 m.l.d. ..	0/5	3/4	4/4	3/4
5 m.l.d. ..	0/5	3/3	2/3	1/3
10 m.l.d. ..		3/3	0/3	0/3

Investigation revealed that the mouse in the British T.A.B. series which died after 2 m.l.d. was a weakly and emaciated specimen that should not have been included in the test.

These results show that, whereas the British T.A.B. vaccine is of the standard normally attained by vaccine made from strains rich in Vi antigen, the Italian vaccines have the limited protective power of a vaccine made from non-virulent strains. Owing to a shortage of mice it has not yet been possible to test the German vaccine, of which supplies have only recently been obtained.

Conclusion

In the absence of any other explanation—and it has been impossible to think of any other which would fit the case—it appears justifiable to conclude that the relative immunity to enteric fever enjoyed by British troops in captivity is attributable to the use of a potent vaccine. Similar immunity is not enjoyed by the Axis Forces, who seem to have a high endemic rate, and among whom an outbreak of considerable magnitude occurred despite inoculation with vaccine of Italian manufacture.

FAMILIAL IDIOPATHIC METHAEMOGLOBINAEMIA

WITH A NOTE ON THE TREATMENT OF TWO CASES WITH ASCORBIC ACID

BY

JAMES DEENY, M.D., F.R.C.P.I.

Lurgan

It has been known for some time that ascorbic acid is related to haematopoiesis in human beings. The nature of the association is not clear. Dunlop and Scarborough (1935) showed that a rise in the number of red blood cells, a fall in reticulocytes, and an increase in haemoglobin followed when vitamin C was given to a patient suffering from scurvy, although the iron content of the diet was unchanged. Barron and Barron (1936) observed that ascorbic acid reduced the red cell count in rabbits suffering from polycythaemia induced by cobalt poisoning. It was thought that polycythaemia is caused by inhibition of the respiration of immature red blood cells and their expulsion from the bone marrow into the circulation as mature non-respiring cells. Kandel and LeRoy (1938) treated two cases of polycythaemia vera with large doses of ascorbic acid without altering the red cell count or haemoglobin level.

Hawley *et al.* (1936) found that sodium bicarbonate raised the renal threshold for ascorbic acid and reduced the amount excreted. In an investigation of the ascorbic acid metabolism in two cases of polycythaemia (Deeny, 1940) it was found that a comparatively low level in the blood was accompanied by the excretion of appreciable amounts of ascorbic acid. On raising the threshold with sodium bicarbonate, large doses of ascorbic acid caused clinical improvement in the two subjects. Impressed with these results, we believe that this treatment might correct a defect in a function of the red blood cells occurring in polycythaemia. One of us (J. D.) observed its beneficial effect in cases in which cyanosis indicated difficulty in maintaining a sufficient supply of oxygen to the tissues—as in congenital heart disease. Clinical changes characterized by improvement in the cyanotic colour and alleviation of symptoms occurred, but the results were somewhat inconclusive and difficult to measure accurately. In a search for subjects in whom objective changes could be demonstrated two cyanosed brothers were discovered who proved to be suffering from familial idiopathic methaemoglobinaemia.

Case I

A clerk aged 29 had been a livid blue colour since birth. There was no history of previous occurrence of the condition in his family. One brother (Case II) was cyanosed. His father, mother, two other brothers, and a sister were healthy and normal. The father died recently from cardiac disease, and a brother from whooping-cough at 6 months. The present subject had had measles, whooping-cough, scarlet fever, and chicken-pox in youth, and lobar pneumonia two years ago. He was in the Royal Victoria Hospital, Belfast, for three weeks in 1933, under Dr. R. Marshall, for investigation, and as a result of spectroscopic blood examination a diagnosis of methaemoglobinaemia was established. No cause for the condition was found, and treatment with potassium permanganate enemata did not improve him.

When we first saw the patient he stated that he felt moderately well, but was very constipated, and breathless on exertion. He could not take strenuous exercise, and noticed that his condition became more pronounced in cold weather. He was keenly aware of his colour, and as a consequence had become rather "nervous." On examination the skin of the face—including the ears and neck—the hands, feet, mucous membranes, and to a lesser extent the trunk, were a deep bluish colour. In contrast to the cyanosis usually found, there was no underlying reddish tint. The skin of his face was coarse and thickened. He was of medium height and slight build, and was moderately nourished. His heart was normal in size and rhythm, and no valvular defects were observed. B.P. 140/90; R.B.C. 5,900,000; spleen not palpable. Haemoglobin estimations carried out with the Dare haemoglobinometer were not satisfactory owing to the abnormal pigment present. The chest was moderately developed, but expansion was poor. No abnormality was found on percussion or auscultation. Mild dyspnoea was noted on exertion. All deep and superficial reflexes, and co-ordination and sensation, were normal. The tongue was moist, with white fur on a blue background; the fauces were congested. The abdomen was normal. Urine examination did not reveal the presence of any reducing or other abnormal substances. An estimation of the oxygen-combining capacity of his blood was carried out by means of the Barcroft method, and was found to be 13.2 vols. per 100 c.cm. (normal, approximately 20 vols. per 100 c.cm.).

Treatment was begun on March 30, 1942. He was given 50 mg. of ascorbic acid night and morning by mouth on the first day, then 100 mg. similarly the next two days, followed by 150 mg. twice daily thereafter. Sodium bicarbonate (2 drachms) was given each day at noon. On the eighth day, when he had taken a total of 2 g. of ascorbic acid, a sudden and noticeable change occurred in his colour, and on the twelfth day his complexion became natural. Since then he has continued with 300 mg. of ascorbic acid and 1 drachm of sodium bicarbonate a day, and has remained normal in appearance. The ascorbic acid was given in graduated doses, as it was uncertain what might result from any possible rapid increase in available oxygen. In this respect the only significant feature was a sudden attack of vertigo on the third day of the treatment, which lasted for 30 minutes, but passed off without ill effect. After one month the oxygen-combining capacity of his blood was 22 vols. per 100 c.cm.

Case II

A shop assistant aged 19. The condition was possibly present at birth, though only to a slight extent; but it became much more pronounced at the age of 11 years. He is not so deeply cyanosed as Case I, is much more strongly built, is athletic, and plays hockey for the local team.

The dramatic change in Case I brought about by the treatment was of such interest that the two men were shown to Profs. H. Barcroft and D. C. Harrison of Queen's University, Belfast, and Profs. J. M. O'Connor, E. J. Conway, and F. Kane of University College, Dublin. As a result it was arranged that Profs. Barcroft and Harrison and Dr. James McMurray should carry out certain investigations during the course of our treatment of Case II. (Details of these investigations will be published elsewhere.) The following is a brief summary of their report:

The diagnosis of methaemoglobinaemia was confirmed by spectroscopic examination of the chocolate-coloured blood. This diluted blood showed an absorption band in the red waveband 632–634 mμ, which disappeared on adding ammonium sulphide. Sulphaemoglobin was absent. The methaemoglobin was intracorpuscular.

Case II was seen before treatment and about a dozen times after treatment began. The aim of each visit was the collection of data on the following: (1) The colour of the skin. Objective records were made by an experienced artist, who painted strips of canvas to match chosen spots on the head and hands. (2) Subjective symptoms. (3) The blood ascorbic acid by Deeny, Murdock, and Rogan's (1942) method. (4) The percentage of the total blood pigments in the form of methaemoglobin calculated from: (*a*) the oxygen-combining haemoglobin by Peters and van Slyke's (1932) gasometric method; (*b*) the total blood pigments by Rimington's (1942) method standardized with blood of known haemoglobin content (Peters and van Slyke's (1932) gasometric method). All determinations were done in duplicate. Some of the results were checked by an independent spectroscopic method. (5) The R.B.C. count. (6) The reticulocyte count.

Treatment began on the evening of May 4, 1942, with 100 mg. of ascorbic acid b.d.s., morning and evening, and 1 drachm of sodium bicarbonate at midday. On the evening of May 20 the dose of ascorbic acid was doubled. During the first month a striking change occurred in the patient's appearance. The slate or battleship blue of his lips and ears gradually disappeared, yielding to the normal reddish tones. The strips of canvas of the tint of the ear-tip, for instance, showed the gradual transition from blue-black to normal beyond any question. He felt great satisfaction that his appearance was now normal. Strenuous exercise was less exhausting.

The blood changes are summarized in the following table. The initial whole-blood ascorbic acid was 0.19 mg. per 100 c.cm. During treatment it rose eightfold in 3 weeks and became stabilized at a level of about 1.73 mg. per 100 c.cm.

Date	Blood Ascorbic Acid mg./100 c cm.	Total Blood Pigments g /100 c cm	% Hb as MetHb	R.B.C. millions/ c mm	Reticulocytes per cent.
4/5/42	0·19	16·9	43		
100 mg. vitamin C b d.s., and ʒi sodium bicarbonate given daily:					
7/5/42	0·29	17·7	40	5·8	
10/5/42	0·46	17·5	30	6·2	5·5
13/5/42	0·68	17·7	28		4·2
16/5/42	0·94	18·9	19	6·1	2·5
20/5/42	1·58	17·3	17	6·0	
200 mg. vitamin C b d s., and ʒi sodium bicarbonate given daily					
23/5/42	1·64	16·5	15		
28/5/42	1·75	16·7	12	5·2	0·5
4/6/42	1·73	14·4	6	5·3	<0·5
30/6/42	1·72	13·7	6	4·4	
13/1/43	1·52	14·75	9·5	5·2	0·25

During the first month, as might be expected from the disappearance of the cyanosis, the proportion of abnormal pigment fell sharply from 43% to 6%. After two months it was still 6% (0.8 g. methaemoglobin per 100 c.cm. of blood). The red cell and reticulocyte counts fell decidedly. This may have been due to the subsidence of a mild secondary polycythaemia stimulated by the diminished oxygen-carrying power of the blood.

The following observations were made on Case I on June 1, 1942, the 63rd day of treatment: blood ascorbic acid, 1.55 mg. per 100 c.cm.; 11% methaemoglobin (sulphaemoglobin absent); R.B.C., 5,080,000; reticulocytes, 0.5%.

Comment

These are the first cases of familial idiopathic methaemoglobinaemia described in Great Britain and Ireland. Abroad the disease has been definitely established in two families, and questionably in another two. Bensley, Rhea, and Mills (1938) reported cases in a brother and sister in Canada, who first became blue at the age of about 11. Their blood contained 5 to 10% of methaemoglobin. An interesting point was that the sister had eight normal children. Lian, Frumusan, and Sassier (1939) reported two brothers in France blue-black from birth with a 35 to 45% blood methaemoglobin, while three other brothers and one sister were alive and normal. A brothe and two sisters—said to have been blue—died young. Bot brothers had an increased red cell volume and a diminishe liver function, which may have been signs of other hereditar abnormalities.

Hitzenberger (1932) reported the case of a mentally defectiv dwarf, aged 23, a "schwerarbeiter," born blue; 40% of hi haemoglobin was in the aberrant form. There was a famil history of two mentally backward dwarf brothers, who ha died aged about 20, and who were said to have been blu The cause of death was unknown. Another probable familia case was that of van Thienen (1933)—a woman aged 33, bor blue, otherwise healthy. Her father was said to have bee blue, but this could not be verified. Isolated cases of wha was probably idiopathic methaemoglobinaemia have bee described by Miller (1930), Dieckmann (1932), van Lier (1933 and Leiner and Minibeck (1935).

Those suffering from the disease usually have little or n physical disability, and first seek treatment for some othe complaint. The blue colour usually dates from birth. Con genital heart disease is often suspected. Physical examinatio shows nothing abnormal in the cardio-pulmonary system. sample of blood is then taken for examination for abnorma blood pigments. The blood is a dark chocolate shade whic persists after it has been aerated. The spectroscope show methaemoglobin. Methaemoglobin may of course appear i the blood for other reasons. Bensley, Rhea, and Mills (1938 classify methaemoglobinaemia as toxic, haemolytic, entero genous, or idiopathic. The toxic form follows the excessiv use of acetanilide, antipyrine, phenacetin, etc. The abnorma pigment usually disappears 24 to 72 hours after discontinuin the drug. The haemolytic form may occur in infection b anaerobic bacteria, in eclampsia, in blackwater fever, etc. Th plasma contains methaemoglobin. Enterogenous methaemo globinaemia (intracorpuscular) occasionally accompanies sever diarrhoea.

At the time we began treatment of the two blue brother we were unaware of Lian, Frumusan, and Sassier's (1939) pape in which they describe the treatment of one of their cases wit 100 mg. of ascorbic acid intravenously, daily for three weeks They tried vitamin C because from the chemical relationshi of methaemoglobin to oxyhaemoglobin it seemed possible tha ascorbic acid might convert the former directly into the latte A free translation of their conclusions reads: "It is absolute certain that this therapy has been followed not only by complet disappearance of the functional symptoms (dyspnoea an headache), not only by sensation of well-being, of euphoria but by remarkable diminution in the abnormal colour. At th same time the proportion of the pathological pigment droppe from 45 to 26% of the total quantity of haemoglobin. . . An interruption of 10 days in the ascorbic acid treatme has been followed by a marked aggravation of the cyanos and a rise from 26 to 35% in the blood methaemoglobin. They have not recorded any further attempts to treat th condition.

We have now observed the effects of treatment on our tw subjects for a period of one year, and during that time both hav had improved health and normal complexions.

Summary

Two cases of familial idiopathic methaemoglobinaemia ar described.

This is the first time this very rare disease has been reporte in Great Britain and Ireland.

A permanent blue colour of the skin, usually dating fro birth, is sometimes the only symptom.

The findings of Lian, Frumusan, and Sassier (1939) tha administration of ascorbic acid diminished cyanosis and me haemoglobinaemia are confirmed.

In our cases the skin colour became normal a few weeks afte beginning daily doses of vitamin C and sodium bicarbonate b mouth. In one case methaemoglobin in the blood fell fro 43 to 6% at the end of the fourth week of treatment. Th change has been maintained in both cases for one year.

We wish to thank the Medical Research Council of Ireland fo assistance; Profs. Barcroft, Harrison, and their associates in Queen' University, Belfast, for the effort and labour which their participatio in this work entailed; and Profs. O'Connor, Conway, and Kane, University College, Dublin, Dr. James McMurray and Dr. Robert Marshall, Belfast, for their interest, advice, and help.

A NEW METHOD OF GRAFTING

BY

P. GABARRO

Former Secretary of the Society of Surgeons of Catalonia, Barcelona; Plastic Surgeon in Charge at an Emergency Hospital

In order that the principles of the new method may be understood it will be useful first to give a short review of the usual types of skin graft. According to the thickness of the graft four types will here be considered: (1) the thin Ollier-Thiersch graft, which has been described—not quite accurately—as only epidermic; (2) the intermediate or split graft, which contains the whole epidermis and a portion of the dermis; (3) a thicker graft of about three-quarters of the skin, which leaves just enough epithelial elements from the sweat and sebaceous glands for the epithelization of the donor area; (4) the whole-thickness skin, or Wolfe, graft.

In the main, two considerations regulate the choice of graft: the thicker the graft the better the quality of the skin obtained; and the thinner the graft the easier it "takes." The area from which the graft is taken should epithelize in less than 15 days if the graft is thin. In thick grafts epithelization may be retarded, and subsequently some scar reaction may spoil the site for further use as a donor area. In the Wolfe graft there is a complete loss of skin, which must be replaced. It will be seen, therefore, that the donor area has its limitations. The kind of graft to be used depends, too, on the local condition of the area to be grafted and on the general condition of the patient, and is not an easy matter to decide upon. One of the chief problems arises when the area to be grafted is very big and the donor area is limited. When the donor area available is small, or the local and general condition of the patient is poor and none of the above-mentioned grafts is considered advisable, use is often made of small rounded grafts, of which there are two types: the thin or Reverdin graft, and the thick or deep graft devised by Davies and commonly called the "pinch" graft. Both are obtained by the same technique. The latter is the one generally adopted in England.

The Pinch Graft

It is necessary to review the pinch graft for the better understanding of this article. It is usually a small graft (3 to 5 mm. in diameter), rounded, deep, and containing all the layers of the skin. To obtain it a needle is used to pick up a cone of skin, which is cut at its base with a knife. The same needle carries the graft to the recipient area. Usually the pinch graft "takes" in raw areas in which no other graft will properly do so. This is why it is so useful. Moreover, it is easy to carry out. Many reasons are given to explain why the pinch graft takes so easily. In my opinion, the main reason is that the grafts are so placed that enough room is left between them to allow of free discharge, and nothing intervenes between the graft and the recipient area. This is an application of the well-known principle of general surgery that no infected area will heal unless there is ample room for the discharge to escape.

From this consideration there arises a conclusion that is one of the main supports of the new method of grafting: *any graft will take more easily, and in poor raw areas, if there is enough room for discharge inside the whole area grafted.* Certainly, then, pinch grafts have many advantages, yet they have several very important disadvantages.

Disadvantages of the Pinch Graft.—(*a*) The donor area of a pinch graft is practically always spoiled as a further donor area for other types of graft. Numerous small scars or keloids are very common. (*b*) A big donor area is necessary if the pinch grafts are placed very close together—sometimes as big as the area to be grafted. (*c*) It is necessary to employ a large number of them, which may prove to be a very long and tedious job. (*d*) Because, through the instruments, contact is established between donor and recipient areas—very often slightly infected—infection may develop in the donor area. (*e*) Usually the site covered by pinch grafts consists of the good skin of the original pinch grafts surrounded by an area of fairly good skin; the rest is more or less keloidal tissue, in many cases with all the disadvantages of scar tissue.

The Ideal Graft.—It seems to me that if the pinch grafts were placed so close together that the distance between them was less than the possible easy spread of the grafts (from 6 to 9 times the original size of the pinch graft), the likelihood of the formation of good skin and quick epithelization would be much greater. Only experience can confirm this. If I am correct in my assumption, therefore, the ideal graft for the type of case mentioned must conform to the following rules:

1. Plenty of room must be left between the grafts for possible discharge.
2. The donor area must not be spoilt, so that it could be used again and again.
3. The graft should take easily—as well as or better than any other graft.
4. The technique must be fairly rapid in use and the number of grafts unlimited.
5. Contact, direct or indirect, must be avoided between donor and recipient areas.
6. The space between the grafts must be less than the possible easy and early spread of the epithelium.

Technique of the New Method

A graft of the desired thickness and from one-sixth to one-ninth of the raw area to be covered is cut from the donor area. It is placed on stiff sticky paper (I have been using the greasy and sterile paper supplied with boxes of "tulle-gras") or any other material of similar qualities, and skin and paper are cut in strips as thin as convenient (Fig. 1). The strips are again placed on the same type of paper, at the distances desired,

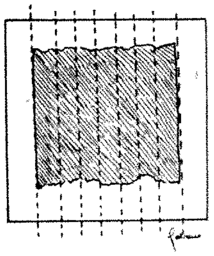

FIG. 1.—The graft, raw side up, is placed on sterile, stiff, sticky paper and cut into strips.

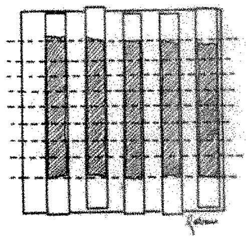

FIG. 2.—The strips, placed on another piece of paper, are cut horizontally.

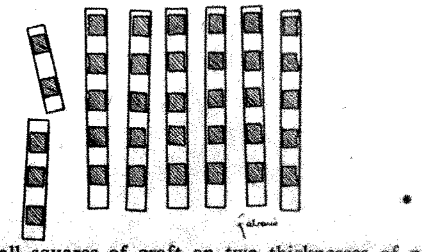

FIG. 3.—Small squares of graft on two thicknesses of paper (only one thickness shown here). The grafts, which retract somewhat, are ready to be placed in position, with the paper.

and the graft and the two thicknesses of paper are cut, but this time at right angles to the first series of strips (Fig. 2). The result is to obtain strips of paper with square grafts, well spread and evenly spaced (Fig. 3). The strips may, of course, be cut narrow or wide, and triangular or any shape desired. Ten cuts in one direction and ten in the other will give 100 grafts, which can be arranged in chessboard fashion, or in a square, a cross, or any desired shape. The chessboard pattern is easy to arrange and is very even in distribution.

Up to now we have employed this type of graft only when the usual graft has failed, when the condition of the raw area made it unsafe to use an ordinary graft, or when there was much limitation of the donor area. Some of the cases were clinically poor.

It is too early to draw final conclusions, but up to the present the results have been striking. The grafts took completely on the following types of raw areas: old burns with bad granulating tissue, after several entire failures of grafts and after recent infection; old lacerations at the heel, also after several failures; a burn five weeks old—one area all round the protruding stump of a humerus; a five-weeks-old laceration of the leg, with much sloughed tissue; 14-days granulation tissue, on recently cut parietal bone; the *bare bleeding bone* of the skull after removal of the necrosed outer wall.

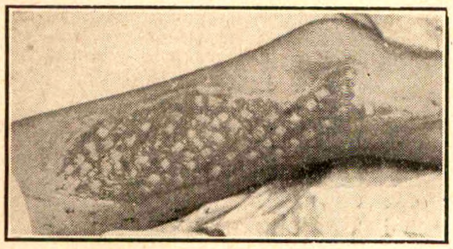

FIG. 4.—Seven days after the grafting operation.

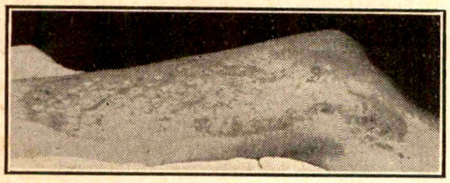

FIG. 5.—Seventeen days after the grafting operation.

The photographs here reproduced (Figs. 4 and 5) are taken from the following case. The main points of the case history are as follows:

Illustrative Case

An engine-driver aged 42 was pinned under a locomotive on Sept. 5, 1942, for 2½ hours while steam blew down upon him. His injuries were third-degree burns of the right arm and the inner aspect of both thighs. His condition on admission to hospital on Oct. 14 was as follows:

Right Arm.—Guillotine amputation had been performed elsewhere. The skin of the stump was retracted for 1½ in. and the humerus covered by fairly clean granulations. Outside the stump there was a granulating area of about 3 in. by 3 in.

Right Leg.—Granulating surface at the buttock, clean, about 7 in. by 4 in. Granulating surface with some adherent slough at the inner surface of the thigh, about 15 in. by 2 in.

Left Leg.—Granulating surface, clean, at the inner side of the thigh, about 12 in. by 4 in.

Oct. 21: Operation (Mr. P. Gabarro).—Local anaesthesia to the donor area; chessboard grafts on burnt areas. A Thiersch graft about 5 in. by 2 in. was cut from the inner side of the left arm with the Blair knife. Following the technique described this graft was divided into 160 square grafts and distributed to the above-mentioned areas. Dressing was carried out with tulle-gras, flavine-paraffin wool, and bandaging with some pressure. Time taken, 2½ hours. Each dressing took a long while.

Oct. 28.—First dressing. All grafts had taken on arm and both thighs; on the buttock only 30% (defect of fixation ?).

Oct. 30.—On arm and both thighs apparently no grafts were lost. They looked healthy, were spreading well, and in several parts had already united, bridging the gaps. On the left thigh there was almost a complete bridge across the whole area.

Nov. 5.—Right arm: All grafts were united, leaving only very small raw spots. Right thigh: Almost completely epithelized. Left thigh: The majority of the grafts were united by epithelium, and only very small raw areas were left.

Nov. 8.—Arm and both thighs completely healed.

Nov. 16.—The patient now up and walking inside the ward.

Nov. 18: Operation.—Local anaesthesia to the donor area. Gabarro's grafts to the buttock. A Thiersch graft was cut with the Blair knife *from the area which was used about a month previously.* The graft was divided into 24 squares and placed on the remaining raw area of the buttock, with some pressure by means of elastoplast. Time taken, half an hour.

Remarks

The time from the operation to the complete epithelization in three areas was 17 days. The first dressing was done on Oct. 28, the seventh day after the operation. The grafts had all taken, but there were still no signs of epithelium growing from the edges. Ten days later, on Nov. 7, the whole area was covered with epithelium.

The surface area of the graft was less than one-tenth of the grafted area, which means—astonishing though it may seem—that during 10 days the epithelium had grown at a daily average of 100% of the original graft. This is not so surprising when one considers that in the three areas in which complete success was obtained there were 120 grafts, each having 26 mm. of edges (6½ mm. × 4), making a total of 312 cm.—much more than 3 yards of growing epithelium edge. That was the position on the first day: once the grafts started to spread the growing area increased. In fact, we obtained in this case a culture of epithelium on the living body.

Conclusion

I think it has been shown that the six conditions which I consider essential for a good graft, in the type of cases mentioned, have been obtained, because in the above case: (1) there was plenty of room between the grafts for possible discharge; (2) the donor area was not spoiled, and was already in use again in less than a month; (3) the grafts took easily; (4) the procedure was fairly quick, considering that it was carried out under local anaesthesia and that the grafts amounted to 160; (5) there was no contact at all between donor and recipient areas; (6) the grafts were placed as close as the possibilities of their growth demanded: in 17 days the raw area was closed.

I wish to express my thanks to Prof. F. Wilkinson for his interest and encouragement; to Mr. A. W. Moule, the dental surgeon of the plastic unit, who was kind enough to take the photographs; and to the staff of the plastic unit, who by their enthusiasm, care in handling the patients, and patience made possible the results obtained.

TREATMENT OF THE FRACTURED GREAT TOE

BY

G. N. TAYLOR, M.B., M.Ch.

Fracture of the great toe is in itself of minor significance in traumatic work; it is, however, the commonest fracture in industry. In the past, many hours, days, and even weeks of disability have followed its occurrence. Its treatment—e.g., splints manufactured from spatulae, or collodion dressings—has been almost beneath the dignity of overworked casualty officers, and many cases are not even referred to the fracture clinic.

Under present conditions the great effort which is being made by both combatants and civilians often means less care in the handling of war weapons and other commodities, so that these articles frequently drop on the not too carefully placed feet, and thus the incidence of this fracture must be greatly increased. It was Mr. Griffiths (1935) of the Albert Dock Fracture Clinic who pointed out the lengthy off-work period that some of these cases demanded—the average duration of incapacity being 18 weeks—and under him a system of treatment has been evolved which reduces this period often to less than 10 days.

Method

The subungual haematoma which forms, more especially with fracture of the distal phalanx, is not large. However, owing to the firmness with which the nail is attached to its bed and the bed in turn attached to the periosteum of the phalanx, the tension developed is great and the pain sometimes excruciating. The nail has on occasion been avulsed in the treatment of such a case, a procedure which is little less than a crime. Such a sacrifice deprives the broken phalanx of an ideal splint and exposes a singularly tender area which will not permit of a return to work for some weeks. In order to save the nail and at the same time to relieve the tension and therefore the pain, it is a simple matter to trephine the nail: a little patience and a sharp operating knife are all that is required. The trephine opening need not be more than 2 mm. in diameter, and should be placed over the most prominent point of the haematoma. With this simple manœuvre the relief is dramatic as soon as the free blood is released. Vaselined ribbon gauze 3/4 in. wide is applied to the toe, and when the fracture is confined to the distal phalanx a plaster-of-Paris thimble enclosing the whole toe provides adequate immobilization. When, however, the proximal phalanx is fractured a plaster toe-splint is fashioned to enclose the sides and plantar surface of the toe; this extends along the medial surface of the foot to about the tubercle of the navicular bone and across the sole of the foot for about half its breadth. The splint is either bandaged or strapped in place. The vaselined gauze lubricates the inside of the plaster and allows an easy and painless removal of the splint. Failure to do this can result in the most tedious and painful task, especially when the blood has leaked under the plaster.

It was always our custom to admit these cases to hospital for 48 hours, with immediate elevation of the limb, and we found that the comfort in each and every case was great. It may be argued that admission to hospital is quite unnecessary. This may be so providing the patient goes home by ambulance and assumes a recumbent attitude with elevation of the limb. Owing to the comfort induced by plaster immobilization and the trephining, these instructions are not always carried out, and treatment in hospital, when space permits, we found more desirable.

The patient is allowed up on the third day, when, by borrowing a boot about two sizes larger than his own, he can accommodate a thimble; the stout leather sole, being unyielding, prevents movement of the toe. The larger plaster sole-splint cannot be accommodated inside an ordinary boot, but it can almost invariably be abandoned for the plaster thimble. The patient is encouraged to use heavy working boots, and by the eighth to the tenth day he may return to work. This date is, of course, variable; sometimes a fracture causes so little incapacity that a return to work on the following day is possible. On the other hand, severely comminuted fractures or grossly lacerated soft tissues will demand a longer incapacity period. This short period of immobilization will not cause any stiffness of the metatarso-phalangeal joint, mobility of which is so essential for comfortable walking.

As with compound injuries of fingers and thumb, conservation of tissue is the great aim. Such aim is no less applicable in the case of the great toe. Excision and débridement are carried out in the same manner as in other compound fractures. When the great toe is severely mutilated and amputation is deemed advisable, preservation of the metatarso-phalangeal joint must always be the goal. The importance of this joint is not always realized, and the simple operation of disarticulation is too often undertaken. Following this procedure, the late result of pain while walking forward on the tread, which entails pressure on the antero-inferior aspect of the metatarsal head, causes many weeks of disability. Where possible a small portion of the proximal phalanx should be left to maintain the integrity of this very important joint. It is almost unnecessary to state that the head of the first metatarsal must be preserved at all costs, because it, together with the remaining metatarsals and the os calcis, forms the tripod on which the weight of the body is borne.

Conclusion

To summarize, the points I wish to make are: (1) trephine and save the nail; (2) plaster-splint, with elevation, for 48 hours; (3) encourage use of a heavy boot during convalescence; (4) condemn disarticulation at the metatarso-phalangeal joint.

Again my thanks are due to Mr. H. Ernest Griffiths for his guidance and encouragement in this and many other matters relating to traumatic surgery.

Medical Memoranda

Bilateral Fracture of the Patella

The following case of fracture of both patellae, treatment of which had an interesting sequel, may be thought worthy of record.

CASE HISTORY

Private A. was admitted to a general military hospital on Aug. 21, 1942, complaining of pain in both knees. At 2 a.m. he had been returning from a dance, travelling as a " passenger " on the crossbar of a bicycle. While descending a steep hill his " pilot " attempted to take a sharp right-hand bend at speed, but at the crucial moment the brakes failed and the bicycle crashed into a stone wall. Private A., by reason of his posture, took the brunt of the impact on his flexed knees.

I examined him at 9.30 a.m. I found a well-developed intelligent youth of some 18 years. He had several abrasions on the knees, both of which were much swollen. The legs were held in extension and any attempt at flexion of either caused severe pain. He volunteered the information that his legs " wouldn't hold him up " after the accident. Shock was entirely absent.

Operation.—Radiographs revealed fractures of both patellae; the right was grossly comminuted, and displacement was severe; the left was a " cruciate " fracture, and displacement was not marked. I decided to remove the right patella. Owing to the multiplicity of dirty abrasions great caution was exercised in preparing the skin, and operation was finally fixed for Aug. 27. Under general anaesthesia the fracture was approached through a midline vertical incision. On separating the fragments an enormous haematoma under pressure was evacuated. Loose fragments were removed and the upper and lower fragments dissected free from the quadriceps tendon. The free ends of the latter were then bunched together with mattress sutures of No. 3 catgut in the manner described by Watson-Jones (1941). The wound was closed and a compression bandage applied. Attention was then directed to the left knee, and it was found that the displacement was easily corrected by direct pressure against the femoral condyles. A mid-thigh plaster cast was applied.

Post-operative Measures.—During the immediate post-operative phase severe pain in the right knee required the frequent use of sedatives, and on the third day transient swelling of the right ankle necessitated slight relaxation of the compression bandage and elevation of the limb, with immediate benefit. The left limb was trouble-free. Stitches were removed on Sept. 5, the wound being soundly healed. Active exercises were begun cautiously on Sept. 7, and the following day the patient was allowed out of bed in a wheelchair. From this time onwards he showed excellent co-operation, and persisted tenaciously at his exercises. The plaster was removed from his left leg on Sept. 21 and he was allowed to bear weight. Radiographs taken on Sept. 28 showed firm union of the left patella in good position; the right knee was clear of fragments and there was no new bone formation. He was discharged on 14 days' convalescent leave.

End-result.—The patient was readmitted on Oct. 15 for a course of physiotherapy, and was finally discharged to duty on Dec. 2. I made a " follow-up " examination on March 19, 1943. He was then in excellent health and spirits. Examination of the right knee showed the wound firmly healed, with painless flexion up to 140 degrees. The left patella was firmly united; the articular surface was smooth, and flexion was possible up to 150 degrees. The patient then volunteered the interesting information that, although naturally left-footed, he now found the right knee not only stronger than the left but also stronger than it had ever been previously. He added that he had no trouble whatsoever with the right knee, but that he got occasional twinges of " rheumatism " in the left knee, especially in frosty weather or after prolonged marching. He referred this pain to the ligamentum patellae. Both quadriceps were equally redeveloped, but tests revealed that the right was undeniably now the more powerful. The efficacy of the " bunching " method of suturing the quadriceps tendon was strikingly demonstrated by the fact that the contours of both knees were indistinguishable.

I have to thank the Director of Medical Services and the Command Medical Officer, Southern Command, for permission to publish this case.

Unusual Case of Obstruction by Worms

The following case may be considered interesting enough to merit publication.

CASE HISTORY

On March 4, about 1.30 a.m., I was called to a child aged 5 years who had become ill on the previous morning. She then complained of abdominal pain and vomiting. This got worse towards night, and she was sent to Nenagh General Hospital. Appendicitis was a suggested diagnosis. On examination the child was restless; her temperature was normal, pulse 100, and respirations 26. She had general abdominal discomfort, most marked about the umbilicus. There was no definite rigidity. Restlessness was the most pronounced feature.

She was operated on that morning about 10.30 o'clock, the anaesthetic used being open ether administered by Dr. Mary Ryan of Nenagh. When the patient was asleep a very distinct and rather large swelling could be felt in the lower abdomen and slightly to the right of the umbilicus. This felt like a possible intussusception. The abdomen was opened by a lateral incision over the appendix and the mass delivered through this opening. It consisted of small intestine, which was under very great tension for an extent of about nine or ten inches. It was bluish, and evidently the obstruction was due to a mass inside and not to an intussusception. The intestine had a rope-like feeling, and at one point what looked like the outline of a long worm was firmly compressed against its wall. I opened the intestine at this point and found that it was packed so tightly with worms that the loops of three or four at once bulged through the incision, which was only three-quarters of an inch long. I drew these out with a tissue forceps, and in a couple of minutes had removed 66 full-sized roundworms! This relieved the obstruction, and although it was now evident that there were other worms in the intestine I closed the incision by two layers of catgut sutures. The child was restless and ill that night, her temperature being 100° and her pulse 148. After that she made a complete and uninterrupted recovery, except for a slight cold which remained a few days. Her temperature was normal on the fourth day and did not again pass 99°. After a week she was given five 2-gr. santonin powders at two-day intervals, when she passed 13 further worms. The child returned to her home on April 2 in very good health.

COMMENT

Notwithstanding the large number of worms which are occasionally found in children, I feel that 79 must be extremely high. The comparatively good health which the child enjoyed before her acute attack is also, I think, rather remarkable in view of the severe symptoms frequently caused by the presence of two or three worms in a child of that age. I have to thank Dr. Ryan for an excellent anaesthetic.

Nenagh, Co. Tipperary. A. D. COURTNEY, M.B., B.Ch.

Macrocytic Anaemia following Partial Gastrectomy

Macrocytic hyperchromic anaemia is a rare sequel of operations involving removal of stomach tissue, and has been described as following total as well as partial gastrectomy (see Gordon-Taylor *et al.*, 1929; Rowlands and Simpson, 1932; Hartfall, 1934). Such operations are probably more often followed by a hypochromic "secondary" type of anaemia (Vaughan, 1932; Hartfall, 1934; Joll and Adler, 1942). As only about a score of well-authenticated cases of anaemia of the macrocytic hyperchromic type as a result of partial gastrectomy have been recorded we consider the subject to be of sufficient interest to publish details of a further example of the condition, which responded to injections of liver extract.

CASE RECORD

The patient, a woman aged 61, gave a history of having had an operation for perforated gastric ulcer 30 years before. She had had a partial gastrectomy performed 15 years ago, when three-quarters of the stomach was removed. A few months before admission to our hospital she complained of pallor and some oedema of her legs.

On examination she was pale, there were signs of chronic bronchitis, and the epigastrium was slightly tender. A blood count (Nov. 4, 1942) showed the presence of a macrocytic hyperchromic anaemia: Hb, 33%; R.B.C., 1,410,000; C.I., 1.2; mean cell diameter, 8.2 μ; mean corpuscular volume, 116 cubic μ; reticulocytes, under 1%; no increase in B.S.R.; W.B.C., 3,200—polymorphs 64%, lymphocytes 36%. As has been described in similar cases, the indirect van den Bergh was negative and the serum was not icteric. A fractional test meal showed achlorhydria, with presence of bile in all specimens. The stools did not contain occult blood. A sternal puncture carried out before the administration of liver showed a typical megaloblastic marrow: myelocytes, 15.75%; metamyelocytes, 2%; basophils, 0.25%; eosinophils, 2.5%; polymorphs, 5.25%; lymphocytes, 2.25%; plasma cells, 1.5%; proerythroblasts, 0.75%; early megaloblasts 13%, intermediate megaloblasts 40.5%, late megaloblasts 16.25% (total megaloblasts, 69.75%).

On the basis of the examination of the peripheral blood and the sternal marrow a diagnosis was made of macrocytic anaemia of pernicious type, following partial gastrectomy, and appropriate treatment with liver extract and iron was started. With this therapy the condition gradually improved, and on Feb. 10, 1943, the haemoglobin percentage was found to be 90 and the red cell count 4,900,000 per c.mm.

We wish to thank Dr. A. D. Rope for allowing us to publish details of this case.

Reviews

SURVIVORS FROM SHIPWRECK

Shipwreck-Survivors: A Medical Story. By Macdonald Critchley, M.D., F.R.C.P. (Pp. 119. 7s. 6d. London: J. and A. Churchill. 1943.

Our great seafaring tradition has been painfully built upon the sacrifices and sufferings of generations of our sailors, and at no time have the stresses of exposure and tribulation been borne with such consistency and to such an extent as to-day. Yet there has always been an unfortunate lack of medical interest in these problems, which we may hope Surgeon Capt. Macdonald Critchley will succeed in rectifying by his admirable little book. He attributes this neglect largely to the increasing rarity of accidents in peacetime, yet shows that although such disasters as the loss of the *Titanic* aroused enormous general interest they never held medical attention. Such neglect has become intolerable at the present time, and it behoves our profession to place its accumulated experience and physiological knowledge humbly at the disposal of the Royal and Merchant Navies in order that some of the elemental hardships may be prevented and others of them assuaged. In this spirit Critchley offers his own contribution. It is indeed a grim story he has to tell; surely never have the depths of human infamy and the heights of human courage and endurance been shown in sharper contrast. Nor is it the courage of ignorance, for many men have endured these trials not once but many times, yet have not faltered.

The author presents his material under the headings of the effects of cold, thirst, hunger, and tropical conditions. He then describes the state of the survivors at the time of rescue, and discusses the psychological aspects of their experiences. Finally he considers methods of mitigation of risks and treatment in general. He succeeds in painting a graphic picture in the small compass of 112 pages, aided by photographs of poignant interest. The longest recorded survival on a float is 3½ days, on a raft 48 days, and in a lifeboat 70 days, though lifeboat voyages of more than three weeks are exceptional. Indeed, if a lifeboat is not picked up within 24 hours there is still a 50% chance of being rescued within five days. Other conditions being equal, large persons stand immersion better than small, since they have a lower ratio of surface area to mass. The tendency of the exposed men to fall asleep in a flexed position should not be regarded or treated as a dangerous complication, for it is comparable to hibernation. When the body warms up after rescue severe pain is felt in the feet, which may not develop for several days, when it becomes persistent, reaching its acme during the second to the fourth weeks. It is worst at night and is increased by any pressure. Naturally, ulcers and gangrene may ensue. A table is given of the symptoms compared with those of trench foot and frost-bite, showing much more prolonged after-effects from "water-bite." Thirst is, after cold, the most distressing and dangerous hardship, and the disastrous results of trying to alleviate it by drinking sea-water are well known. Food is of very secondary importance, for adequate water supply is the dietetic factor which will determine survival; and the limited stowage space within life-saving contrivances could be more fruitfully devoted to water than to food would the layman but realize it. On physiological grounds there is a case for advocating fats, and especially carbohydrates, to the virtual exclusion of proteins. The severe cold of the North Atlantic may overwhelm a man in a comparatively short time, whereas in a hot climate a high morale will triumph over the greatest physical hardships. Anything up to two weeks in a boat is then borne well, despite minimal food and water. In the Tropics a 50% survival rate has been recorded after almost entire submersion for 32 days. Blistering, salt-water burns, and boils, and even gangrene, may occur, and the risk from carnivorous fishes is by no means negligible, though the dreaded shark is really less deadly than the "tiger fish."

On rescuing, the survivors will probably present a macabre picture wherein shock, cold- or heat-prostration, emaciation, dehydration, local tissue destruction, or focal infective lesions are conspicuous. Almost certainly a mental reaction will be present—whether of simple relief or excited elation—it may well be with a background of confusion, mild delirium, apathy, or simple depression. Surgeon Capt. Critchley has done good service in emphasizing what extremity the human body is capable of withstanding and impressing upon us anew our deep debt to our seamen.

GENERAL SURGERY, 1942

The 1942 Year Book of General Surgery Edited by Evarts A. Graham, M.D. (Pp. 848; 306 figures. 19s.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co.

The yellow jacket of this yearbook reads like an examination paper of some 20 questions, but the answers to these can be found within. We are invited to test ourselves on "a 10 minutes quiz" consisting of such questions as, What is the one safe inhalation anaesthetic ("anaesthesia" is the word actually used) for patients with acute respiratory disease? and, Is there any hereditary factor in the development of ingrowing toe-nail? All this probably has some selling value, but to the discerning, and to those already familiar with this valuable perennial, is quite unnecessary. To our readers the value of the yearbook of surgery is too well known to need any such boosting.

Like its predecessors, the present volume sums up well the year's contributions to surgery, and contains condensations of many of the most important papers. In an introduction the well-known and distinguished editor reminds us that much of the surgical literature of the last year has been devoted to war wounds, and yet most of the articles reveal nothing essentially new. Since the last war, chemotherapy and the tannic acid treatment of burns are perhaps the two outstanding contributions to surgery, but there is still no general agreement as to what is the best local treatment for severe burns.

In a brief review such as this it is difficult to know what to choose as representative samples of its contents; but perhaps some idea of these will be gained by referring to one or two at random, such as the evaluation of the Miller-Abbott tube, the surgery of tumours of the pancreas, and the present position of the surgical treatment of hypertension. The busy surgeon will need this book to keep him in touch with recent developments.

UROLOGICAL PRACTICE

The 1942 Year Book of Urology. By Oswald S. Lowsley, M.D., F.A.C.S. (Pp. 456. 19s.) Chicago. The Year Book Publishers; London: H. K. Lewis and Co.

This book is a valuable companion and should be near to the hand of those who are anxious to keep pace with urological progress. No advance in urology worthy of mention is omitted. The *Year Book* is, in fact, a reference library, containing in condensed form not only the recent views of recognized authorities but also where and when these views have been published. "General Considerations" occupy the first 65 pages. Under this heading a variety of subjects are discussed, including injuries, infections, calculi, tumours, and anaesthesia. There is perhaps a tendency towards repetition of these discussions in the later pages devoted to specific organs. However, no change in the arrangement of the contents would be an improvement. Many useful hints are given under the various headings. For example, it is suggested that, whereas rupture of the bladder or urethra requires immediate operation, injuries to the kidney are as a rule better left alone. In order to avoid delay in the diagnosis of urinary lesions it is recommended that every patient, whatever the nature of the trauma, should be made to void or be catheterized as one of the first steps in the general examination. This is sound fundamental advice. Occasionally, however, catheterization is misleading. The reviewer catheterized a patient with multiple widespread injuries. The result appeared satisfactory. Later it was found at operation that the catheter on two occasions had passed through a rent in the bladder wall, and that fluid, including urine, was drawn from the peritoneal cavity.

The book contains much valuable information on the subject of sulphonamide therapy, and draws timely attention to the many dangers and complications which may arise from this therapy in treatment of infections of the urinary tract. Injuries and diseases of the kidney and ureter are discussed in full measure. There are useful reminders of the anomalies and malpositions which are such ready traps for the unwary diagnostician. In the final pages a good account is given of transurethral resections and of the surgery of the prostate and the genitalia.

War brings patients with multiple injuries. The patient with a fractured femur and lacerated lung may also have a ruptured bladder or urethra. He will still survive if handled with skill and judgment. The general surgeon at the front line—and nowadays the front line is everywhere—will strengthen his resources by having the *Year Book of Urology*, in company with a few similar volumes, close at hand. He will be familiar with most of the contents, but sometimes he will need mental refreshment, and after a long war service may wish to make quite sure that, from year to year, he has kept in pace with the times.

Notes on Books

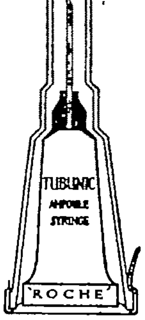
Dr. F. M. R. WALSHE's book *Diseases of the Nervous System Described for Practitioners and Students* is by now well known to many readers. A feature, noted in these columns when the book first appeared in 1940, is the avoidance of complex and technical terms so far as possible. As an introduction to clinical neurology it is written in simple and direct language which the least experienced in this branch of practice should be able to follow. In the accounts of the commoner nervous diseases, the degree of detail given varies according to the relative importance of each malady in the general practice of medicine. A third edition has now appeared (E. and S. Livingstone; 15s.). Dr. Walshe has thoroughly revised the text, and has introduced brief new sections on ocular movements and on the pituitary–hypothalamic complex, on infantile hemiplegia, and on sinus thrombosis; recent work on the aetiology of acute poliomyelitis is summarized. There are some new diagrams and reproductions of radiographs.

The "Practitioner" handbook entitled *Minor Medicine*, under the editorship of Sir Humphry Rolleston and Dr. Alan Moncrieff, is published by Eyre and Spottiswoode at 16s. Most of the twenty-four chapters have already appeared in the pages of the *Practitioner*, but in each case the author has revised his material for its reappearance in book form. Throughout these miscellaneous practical contributions to everyday medicine the point is made, directly or indirectly, that maladies commonly spoken of as "minor" may nevertheless play a major part in the discomfort of the individual; and the editorial preface enforces the maxim that the man rather than his malady should be treated, and that it is the peculiar province of general practitioners to observe and note the early human reactions to adverse factors and to act on the principle *obsta principiis*.

With reference to Dr. PERCY TURNER's *Tropical Medical Manual* noticed in this column on May 29 we are now informed by the Salvation Army International Headquarters that the price mentioned is only for missionaries, and is plus postage. The manual cannot be supplied to the general public, nor to bookshops for re-sale

Preparations and Appliances

AN AMPOULE SYRINGE



The "tubunic" ampoule syringe illustrated in this column has been evolved as a result of numerous conferences between Roche Products Ltd. (Welwyn Garden City, Herts) and advisers of the medical services. Since the first British "tubunic" syringe was introduced improvements have been effected in several directions, and the latest model is claimed to be an advance on all its predecessors. The figure gives a diagrammatic representation of the new safety outfit. This ampoule syringe is protected by a transparent plastic case which carries a collapsible tube with hypodermic needle in position, the entire apparatus being kept unsoiled by means of a basal cap. In emergency the cap can be removed instantly, the stylet used to pierce the container, and the released solution injected by compressing the tin container.

PROTEOLYSED LIVER (EVANS)

Evans Sons Lescher and Webb Ltd. announce that, in response to numerous inquiries regarding proteolysed liver (see *British Medical Journal*, May 29, 1943, p. 655), the preparation is not yet available commercially. Limited supplies are available, however, for *controlled* clinical trials, and requests for samples should be addressed to the medical director, the Evans Biological Institute, Runcorn, Cheshire.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 12 1943

T.A.B. VACCINE VINDICATED

It is notoriously difficult to obtain conclusive evidence of the value of vaccination against enteric fever. In civilian populations the incidence of the disease and the proportion of vaccinated persons are both usually so small that evidence can be obtained only during an epidemic, and results of this nature are complicated by the possibility that infection may occur before or during immunization. Armies are our most fruitful source of information, but conclusions cannot be based on comparisons between different wars, in which the frequency of enteric fever was influenced by sanitary conditions as well as by the state of immunity of the soldier. A valid comparison can be made only between vaccinated and non-vaccinated men in the same army and under the same conditions. The presence of a small proportion of men in the British Army in France during the war of 1914-18 who had refused or otherwise escaped immunization provided this necessary control; the proportion was small, but the total number in so large an army fully adequate, especially in the early part of the war. The most striking figures refer to the incidence of typhoid fever in the year 1915, when the incidence was more than ten times greater in non-vaccinated men: there was comparatively little difference in the incidence of paratyphoid, and the vaccine used until then had contained typhoid bacilli only.

Since the last war much has been done to improve the immunizing power of T.A.B. vaccine, and the Royal Army Medical College has led the way in requiring that the cultures used shall be fully virulent as well as smooth. That such a vaccine has greater immunizing power can be proved by protection tests in mice, and strong presumptive evidence of its practical value was furnished by the very low and diminishing frequency of enteric fever in the Army in India. It is this vaccine which has hitherto been used in the Army during the present war—that is, a heat-killed and phenol-preserved vaccine made from virulent cultures. Whether the alcoholized vaccine advocated by Felix and shown by him to stimulate the formation of Vi as well as O agglutinin has a greater protective effect has yet to be proved in the field. Striking testimony to the value of the present R.A.M.C. vaccine comes in an account of enteric fever in the North African theatre of war by Colonel J. S. K. Boyd at page 719 of our present issue. This concerns prisoners' camps on both sides. In an enemy camp near Benghazi which at one time contained as many as 24,000—mainly British—prisoners, where the sanitary conditions were bad, and dysentery attacked a large proportion of the men, no cases of enteric fever were recognized, although the disease existed among enemy troops in the neighbourhood. The freedom of British prisoners from enteric fever occasioned surprise among Italian medical officers in Benghazi. Contrasted with this is the course of events in a British camp containing mainly Italian prisoners, also in large numbers. Here, in spite of sanitary precautions, cases of enteric fever occurred in considerable numbers, and continued to occur in spite of immunization with captured Italian T.A.B. vaccine. Only when the prisoners were later given R.A.M.C. vaccine did the incidence of the disease fall to a low level. Particularly interesting is the analysis of cases among prisoners taken at El Alamein: more than half of these attacks developed within ten days of capture, showing that the disease was active among the enemy at the time of the battle. Of the remainder a majority occurred so soon after vaccination that its full protective effect could not have been attained.

These observations are not all of a kind to withstand statistical analysis: some indeed are not strictly numerical at all, and the conditions under which they were obtained did not lend themselves to the collection of exact and unassailable data. Of their general significance there can nevertheless be no doubt, and there is neat and gratifying confirmation in the experimental comparison made between Italian and British vaccines. By mouse protection tests it was shown that, although the R.A.M.C. vaccine produced resistance to 10 m.l.d. of culture, neither of two brands of Italian vaccine saved the life of a single animal so infected. These results, both clinical and experimental, deserve the serious notice of all R.A.M.C. officers responsible for the inoculation state of their units. All inoculations in the Army are on a voluntary basis, and how efficiently they are carried out depends much on the zeal of the individual officer concerned, which in turn will depend in part on his own conviction of their usefulness and necessity. Colonel Boyd's paper affords an ample basis for that conviction, and T.A.B. vaccination should be regarded throughout the Army not as a tiresome formality but as a safeguard which may materially affect the success of an entire campaign.

PLANNING FOR MENTAL HEALTH

Amalgamation of voluntary associations is always a difficult matter, not from lack of good will but because of wide variations in their origins and constitutions. In the broad field of mental health the Central Association for Mental Welfare was formed in 1913 to undertake community care of defectives and to supplement the work of statutory authorities. This Association has enlarged its borders and is now the focus of those whose lack of social co-operation prevents them from realizing the full responsibilities of citizenship. The war of 1914-18 brought to the surface many forms of mental ill-health that had been buried during the period of shock and strain. With the object of preventing these disorders by education and propaganda a new voluntary association was created shortly after the war—the National Council for Mental Hygiene. This body has carried out important pioneer work in public education and in directing attention to the social and industrial background of mental illness. A third voluntary body, the Child Guidance Council, was formed later to develop the far-reaching discovery that many mental troubles and social maladjustments have their origin in early childhood. This Council received generous support from the Commonwealth Fund of America and was able from the start to develop clinics and to offer training facilities for both medical and social workers.

With all these extending and diversified branches of the work it was inevitable that overlapping, with its consequent waste of effort and money, should occur; to remedy this a bold scheme of amalgamation was undertaken by the leaders of the voluntary movement. Unfortunately, the present war cut short the scheme before it could be perfected, but in the meanwhile an Emergency Committee, with representatives from the Central Association of Mental Welfare, the National Council for Mental Hygiene, and the Child Guidance Council, was formed in 1939. This committee foresaw many of the problems created by the war and was ready to meet them, and the work it has done up to now has been invaluable. After the evacuation of children it set up local organizations to assist authorities in reception areas in dealing with "difficult" children. They also found special billets for nervously unstable cases and provided specially trained supervision for hostels in which difficult children were housed. Many authorities showed their appreciation of the work by appointing permanent officers to continue what had been begun as a voluntary contribution to the war effort. This has again been a successful demonstration of voluntary and statutory bodies working together for the common good. In connexion with the latest Government regional development of medical services the committee has arranged for regional representation in its own field which links up with existing mental health organizations. From all over the country the hospital authorities—Army, R.A.F., and E.M.S.—have increasingly sought help from the committee in after-care work for mental cases in the Services, and advice has been asked in connexion with very many civilians suffering mentally as a result of the war.

Emboldened by its successful career the Emergency Committee again considered the possibility, even in war-time, of closer co-operation and greater permanency, and a Provisional National Council for Mental Health has just been formed under the chairmanship of Sir Otto Niemeyer. This Council is to act as a single central body covering the whole mental health work of the three participating associations. It should accomplish much and prove to be a most important achievement in centralized control. News of its work will be recorded in *Mental Health*, the journal of the constituent bodies. The Mental After-Care Association, which was for many years the only organization of its kind, has announced through its chairman that it is in full sympathy with the ideals of the Provisional National Council.

EXPOSURE AND THIRST AT SEA

There are two most essential needs for the shipwrecked sailor exposed in boat or raft, and for the airman who has had to take to his dinghy: the first is a protective suit to prevent death from cold, and the second an adequate supply of water. As was stressed in the excellent M.R.C. "guide" for the shipwrecked,[1] food is a less pressing need, for with body warmth conserved and water enough to drink a man can keep alive without food for many days. Sir Leonard Hill pointed this out when he was asked by the Board of Trade some twenty years ago what food ought to be supplied in lifeboats and rafts fitted on passenger ships, and he and Dr. Argyll Campbell then carried out experiments on the East Coast with a one-piece dress designed for them by Sir Robert Davis. This was made of thin waterproof material and enclosed the whole clothed body; it lessened the body heat loss by one-half when the wearer was exposed to cold wind and the splashing of waves. In 1940 Sir Leonard Hill drew the attention of the Liverpool Association of Steamship Owners, and of the Ministry of Transport, to these experiments published in an M.R.C. report on the katathermometer, body heat and efficiency. For use in lifeboats and rafts it was determined at the Ministry of War Transport that a three-piece suit was more convenient, consisting of trousers, tunic, and hood, made of thin oilskin and of light weight. The whole dress folds up into the hood, and is carried, as a gas mask is, so as to be available on any emergency. The dress is coloured bright yellow and is thus easily seen from the air. In an admirable waterproofed book of advice provided by the Ministry for each lifeboat or raft full instructions are given as to the use of this dress and all other means of saving life. About a quarter of a million protective suits have now been issued to merchant seamen, and reports on their utility have been most striking. The dress protects the wearer from the tropical sun no less than from cold.

The Ministry of War Transport likewise recognized the need to provide as much fresh water as possible, and directions are given for catching and storing rain. The hood of the protective dress comes into use for this purpose. A simple form of still has recently been designed in which compressed briquettes or paraffin can be burned. Working 10 hours a day, such a still produces in 14 days 70 gallons of drinking-water from sea-water—about twice the amount carried in a lifeboat intended to hold 40 people, giving in all more than a pint and a half a day for each person. The still can also be used to provide hot drinks and for drying clothes. Briquettes can be stored in odd corners of the boat. In the U.S.A. another and most ingenious method has been devised for obtaining the necessary water, and that is the catching of fish, chewing the raw flesh, swallowing the juice, and discarding the solid not needed for food.[2] Salt sea-water cannot be drunk without danger to life, and the suggestion put forward that it can be injected into the lower bowel, and water safely absorbed from there, has been proved wrong. Animal life in the sea has, however, the power of forming a body fluid, without excess of sea-water salt, similar to human body fluid. With the help of a press, minced raw flesh of sea-fish yielded about 25% of its weight as juice. The carrying of a press is, however, not required, for the teeth in the mouth can do the work. Two sailors who volunteered for the trial lived for 10 days in full health on fish juice so obtained and the food rations supplied in a lifeboat. Now all the rubber dinghies for the Air Force, and the lifeboats and rafts of ships, are being supplied in the U.S.A. with fishing tackle; for bait pork rind is used which has been treated so that it will keep. Fish tend to gather under any shelter such as seaweed or a boat to escape the gulls, and big fish follow small ones, so there is every chance of good catches. With hooks, lines, leads, and bait are included a grapple and a small harpoon, which, attached to an oar, can be used for spearing birds, turtles, or sharks. There are provided also a dipper for catching small fish for bait, and a knife with a wooden handle which floats. The kit weighs only a few pounds and contains a small waterproof book of instructions. About 83,000 small kits have already been put in dinghies for aeroplanes, in rafts and boats; and of a larger kit about a quarter of a million are being prepared.

The introduction of the fish-juice method of obtaining water is due to Mr. Pinchett, a former Governor of Pennsylvania, and now 78 years old. A traveller used to living on the wild, he ascertained that Polynesian natives are in the habit of getting along without water for a good while by chewing raw fish flesh and swallowing the juice. He was able to secure the attention of the Naval Bureau and get the method tried out and taken up. No doubt our own Ministry of War Transport, Admiralty, and Air Ministry will follow the example of the U.S.A. and provide fishing tackle for lifeboats and rafts, which will occupy the interest of the shipwrecked while awaiting rescue, as well as providing fish juice for preserving their life.

YOUTH REGISTRATION AND HOURS OF WORK

By Order under the Defence Regulations, all young persons aged 16 or 17 were registered in 1942 with the object of enabling local education authorities to make contact with them and to encourage them to find the best way of fitting themselves to do their duty as citizens and of assisting the national effort. A recent report,[1] presented to Parliament by the President of the Board of Education and the Secretary of State for Scotland, affords a brief but interesting summary of the main results of the inquiry. Altogether 1,442,361 boys and girls were registered in England and Wales, and about 800,000 of them were invited to an interview, of whom 610,600 attended. (Corresponding figures were obtained in Scotland.) The local education authorities set up small panels composed of two or three men or women who met on one or two evenings a week for several months for the purpose of the interviews, and as a rule about three-fourths of the young people were advised to join one or other of the youth organizations in the locality. Probably about half of them accepted the advice, the favourite choices of the boys being the A.T.C., Sea Cadets, Army Cadets, Home Guard, and Youth Clubs; and of the girls, Girls' Training Corps, First Aid Units, and Youth Clubs. Of those who did not respond to the advice, a number said that they were too tired owing to long hours of work, coupled as they often were with the fatigue of long times spent in daily travel. Quotations are recorded from the statements made by various interviewing panels of the strain upon young people from the excessive work so many were undertaking. On the farming side, for instance, the hours worked usually equalled, or exceeded, the longest demanded by the industry, owing to the shortage of labour. Extraordinarily long hours were recorded by some boys and girls who were doing two jobs, such as factory work by day and service in fish-and-chip shops or cinemas in the evenings. Physical tiredness was more evident with the girls than the boys, the more alarming symptom being that of mental lassitude. A considerable body of the evidence indicating the strain of long hours was published in the summer of 1942, and probably this had a substantial restraining influence on those in authority, for a report made by the Ministry of Labour showed that in January, 1943, very long hours in factories were comparatively rare. Ten sample areas were investigated, and it appeared that about half of all the youths and girls were working 48 hours or less a week, whilst a quarter were working over 52 hours and 5% over 55 hours. No recent evidence was adduced by the committee about the hours worked in shops, but it is to be remembered that on occasions of seasonal pressure the young people may be asked to work for 60 hours a week. In factories and in employments covered by the Young Persons (Employment) Act, 1938, they are ordinarily limited to a maximum of 54 hours a week, but the Minister of Labour has power in wartime to make Orders which have the effect of modifying the peacetime provisions so far as may seem expedient in the national interest.

The evidence obtained by the interviews has stimulated the Government to make definite proposals for improving wartime conditions, and it has decided "to review immediately . . . all cases of wartime relaxations of hours of employment with the object of providing that (*a*) young persons of 16 and 17 years shall not be employed for more than 48 hours in any week except where the hours allowed were necessitated by the particular circumstances; and, similarly, (*b*) that young persons of 14 and 15 years shall not be employed for more than 44 hours a week." Other proposals relate to canteens, the question of double employment, and other factors designed to improve working conditions. We must be thankful that the Government has at last arrived at its decisions, though we cannot forget the long delay.

TYPHOID FEVER DUE TO INFECTED CHEESE

The question is sometimes asked whether butter and cheese are not as often responsible as raw milk for human cases of tuberculosis due to the bovine type of bacillus. The survival of tubercle bacilli in these products depends mainly on three factors: how heavily the original milk is infected, whether raw or pasteurized milk or cream is used for manufacture, and how long after preparation the articles are stored before they are eaten. Numerous observations made by the early bacteriologists showed that tubercle bacilli died out gradually in both butter and cheese, owing presumably to the effect of acidity. The length of time during which they could be demonstrated varied from a few days to several months, depending to some extent on the degree of the original infection. As a rule, however, they were all dead within two months. It follows, therefore, that neither butter nor cheese which has been stored at the usual temperatures is likely to cause human infection unless eaten fairly soon after manufacture. On the other hand, farm butter and soft cheeses, which are often consumed within a few days of production, are both potentially dangerous. In this country before the war over 80% of the butter was imported, and almost without exception imported butter was made from pasteurized cream. Of the butter manufactured in this country, the greater part was made in factories from pasteurized cream, and only a very small proportion on farms from raw cream. The consumption of soft cheese was trivial compared with that of the hard cheeses. It could therefore be stated with some assurance that the risk of contracting tuberculosis from butter or cheese was almost negligible compared with that from raw milk or cream. The war, however, has brought about a change. Considerably less butter is consumed, and the manufacture of farm butter for sale has practically ceased. Butter is therefore even less liable than before to be infective. With cheese the position is more complex. Cheddar cheese used to be ripened for 5 to 9 months or so. Two types of Cheshire cheese were sold—one a quick-ripening variety marketed between 14 and 28 days after manufacture, the other a long-keeping variety marketed between 3 and 5 months after manufacture. Now the ripening period has been controlled and, on the whole, shortened. Small quantities of Cheddar cheese may be marketed within 3 months, and practically all Cheshire cheese within 1 to 3 months. Against this consumption of less fully ripened cheese must be set the closure of several of the smaller cheese-making units which were using raw milk, resulting in an increased proportion of cheese coming from the larger units, which usually pasteurize their milk. In addition, cheese is reaching this country from the United States which has been stored there in a refrigerator for some weeks or months, and is put on to the English market within a month or two of its arrival. The rate of death of tubercle bacilli in refrigerated cheese is not known with certainty, but it is almost sure to be less than in cheese ripened at the usual temperatures.

The danger of eating unripened cheese is exemplified by a recent epidemic of typhoid fever in Manitoba.[1] Dr. M. Bowman, who was responsible for its investigation, says that there were three separate outbreaks affecting three different places, between the end of December, 1939, and the end of March, 1940. Altogether about 100 persons contracted the disease. The only common foodstuff was cheese prepared at a given factory. Examination of the personnel on all the farms supplying milk to the factory revealed the existence of a persistent carrier of typhoid bacilli who had lately come to the district and had started to ship milk about a month before the onset of the first case. He continued to do so till he was stopped at the beginning of April. Infection of the cheese may also have occurred from the first assistant cheese-maker, who developed typhoid fever in the middle of January. Inquiry into the mode of preparation of the cheese showed that it was allowed to dry for 7 or 8 days, then waxed and shipped to the wholesaler about the tenth day. The cheese was given no proper period of ripening, and may well have reached the consumer within 2 to 3 weeks of its manufacture—a time too short to ensure the destruction of even the typhoid bacillus. The remedy proposed by Dr. Bowman to combat such a risk in future is to supervise milk for cheese-making as rigidly as that intended for consumption in the liquid state, and to insist either on pasteurization of the milk before it enters the cheese vat or on adequate ripening of the cheese before it is sold.

A BIRTHDAY IN MEDICAL JOURNALISM

With its June issue our contemporary the *Practitioner* completes its seventy-fifth year. Journals, unlike individuals, do not grow old as the result of the mere passage of time, but an existence of three-quarters of a century excuses one privilege of age—that of looking backwards. The history of the *Practitioner* is remarkable for its succession of editors. With the exception of the first editor and founder, F. E. Anstie, who died nearly seventy years ago, just after he had become first dean of the London School of Medicine for Women, all the editors have been men whose names are familiar to the present generation of medicine. Sir Lauder Brunton, the author of a famous textbook on pharmacology and therapeutics, succeeded Anstie in the editorship in 1874. After a few years he was joined by Sir Donald MacAlister, afterwards president of the General Medical Council. A third editor was added a few years later in John Mitchell Bruce, and this distinguished triumvirate was in editorial control for eleven years. Then, with a change of ownership, the direction passed to Sir Malcolm Morris, the well-known dermatologist, and after him to W. C. Bosanquet, a classical scholar and philosopher as well as a physician. He reigned until 1904, after which, for a number of years, the names of the responsible editors did not appear upon the title pages of the volumes. In 1924, for two years, Sir Arbuthnot Lane was controlling editor, and from this time, over a period of eleven years, Mr. R. Scott Stevenson was actively associated with the editorship. In 1928 Sir Humphry Rolleston (who has written an interesting introduction to the birthday issue) became editor, and with him, since 1934, Dr. Alan Moncrieff has been joint editor. The original subtitle of the *Practitioner* was "A Monthly Journal of Therapeutics." It was regarded from the first as a special medium for information about remedies; its monthly articles upon the treatment of disease and its epitome of articles upon this subject in foreign journals were highly valued at the time when it was realized that, in the words of Sir Thomas Watson, then President of the Royal College of Surgeons, "we want to know distinctly what is the action of drugs, and of other outward influences, upon the bodily organs and functions." The first number contained an article by Dr. (afterwards Sir) J. Russell Reynolds on the therapeutic use of bromide of potassium, which at that time, after having been a fashionable remedy, had, in the manner of fashionable remedies, come under a cloud. In the first volume there is an article by Sir Benjamin Ward Richardson on blood-letting as a point of scientific practice. Sir Clifford Allbutt appears in the second volume, writing on the subcutaneous injection of morphia. Several articles in the early volumes are by E. A. Parkes on the effects of alcohol. The index of the 150 volumes is a short history of therapeutics. We congratulate the joint editors not merely on having reached an interesting date but on a consistent record of high achievement. To have published 900 consecutive monthly issues of such high quality and practical usefulness is legitimate ground for satisfaction.

THEOPHYLLINE FOR ASTHMA

The chronic asthmatic has to be his own doctor, at least to the extent of being able to administer his own adrenaline. Even the most formidable attack may be averted by early treatment, and the asthmatic becomes by constant practice the best judge of his own condition. Among methods of administration, inhalation of 1 in 100 adrenaline from a fine spray has proved useful in aborting early attacks in individual cases; and the intramuscular injection of adrenaline in oil leading to a prolonged liberation of the active constituent has sometimes been effective. But when a patient has struggled on with his occupation in the face of increasing dyspnoea, and has delayed effective measures until too late, adrenaline may lose its efficacy and 10 to 50 times the normal dose prove necessary, spread out over a number of hours. The time involved is a serious matter, for the patient should be under constant supervision.

Most asthmatics know by experience that hot coffee is an excellent palliative in the early stages of an attack, and as long ago as 1912 Pal showed that caffeine would reduce the bronchial spasm induced in guinea-pigs by peptone. It was subsequently found that caffeine also stimulates the medullary centres. Recently other purine derivatives have been used in the treatment of bronchial asthma, and theophylline seems the most efficient. In 1931 Hermann and Aynesworth successfully treated a refractory asthmatic with theophylline injected intravenously, and since then many other authors have had similar success. Thus Carr[1] has treated 22 patients with status asthmaticus who were received as acute emergencies and who did not respond satisfactorily to adrenaline. In half of the cases 0.48 g. theophylline in 2 c.cm., given intravenously over 2 minutes, brought immediate relief. In the remainder the effect was evident within half an hour and lasted for a variable time, from one hour upwards. In 5 cases out of the 22 there was no recurrence: that is to say, a single injection had effected an immediate cure. In about one-third of the cases there were undesirable toxic reactions, such as dizziness, nausea, vomiting, "pounding of the head," or pain in the chest; these were transient and unaccompanied by gross cardiovascular changes. No fatalities have been recorded, either here or elsewhere in the literature, with this dosage. These results are most encouraging, though the exact mode of action of the theophylline is still under dispute. It has been suggested that it restores the sensitivity of the tissues to adrenaline in some unexplained way. It seems more probable that by a direct action on the bronchi and upon the medulla it breaks the vicious circle for a sufficient length of time for the patient to recuperate. While it is at present advisable to restrict the use of theophylline to the refractory cases until further experience has accumulated, it may well be that in the future it will prove to have a still more extended use.

FUTURE OF MEDICAL SERVICES

ADDRESS BY Dr. CHARLES HILL

A discussion meeting under the auspices of the Catholic Organization known as "The Sword of the Spirit" was held at Essex Hall, London, on June 5 to discuss the future of medical services in the light of Assumption B of the Beveridge report. The chair was taken by the Bishop of Lamus (Rt. Rev. Edward Myers).

Dr. CHARLES HILL, Deputy Secretary of the British Medical Association, who was the principal speaker, said that the Government, in the debate in February last, had accepted Assumption B and had elaborated it in two ways—one that the service should be administered by a Government Department, and the other that its local administration should be through major health authorities grouped for the purpose. The Government had then started non-committal consultations with various interested groups—local authorities, hospitals, and the medical profession—and had pledged itself that when it had made up its mind in a tentative way it would publish its provisional conclusions in a White Paper which would be submitted to the interested groups and to the public.

In these non-committal conversations, conducted in parallel with the different groups, no secret was made of the desire, powerful in the bureaucratic mind, to establish a whole-time State salaried service administered centrally by a Government Department and locally by grouped local authorities. One fundamental issue which must be resolved by the public was whether such a general development was in the public interest. Was it in the public interest that what was now a comparatively independent profession should be translated into a branch of local government service?

The Doctor–Patient Relationship

One consideration, said Dr. Hill, seemed to him to be paramount—namely, that the relationship essential between doctor and patient was a single relationship in which the doctor's loyalty was to his patient and not to any third party, certainly not to the State. But free choice of doctor, resulting in unequal demands upon different doctors according to their attractiveness to their patients, could not continue in a whole-time State service. Free choice, with a single contractual relationship, was essential. The medical profession had no reason to be ashamed of the quantity or quality of the service that had been rendered to the community under this arrangement in the past and present. Unless free choice of doctor was carried over into the new administrative set-up the change would be for the worse and not for the better.

But there were other considerations. Medicine should be divorced as far as possible from party political affairs. With the State not only the provider of medical and allied facilities but the master and employer of the hitherto independent profession which rendered the service, there would be greater danger of political interference with medicine. Take the central administration. They did not want a Minister whose claim to political favour would lay in the brilliance of the gloss he could put on his report of the country's "stubborn good health." When he read such statements he sometimes for the moment forgot that the Minister was not himself responsible for such a result, and that it was due to the spirit of the people, to say nothing of the service of doctors and nurses! But that sort of thing gave an inkling of what awaited them when the State became the universal employer.

As for local government, there were many men and women who gave fine and disinterested service in that field, but it must not be pretended that local government was satisfactory in all places. There were all too many examples of local government as a party theatre, with political considerations and local prejudices intervening, and there was no guarantee that the calibre of members of local authorities was of a kind capable of the management of personal health services. Yet in the Ministerial mind to-day there was an assumption that the centre-cum-local health authority set-up, because of democratic election, was suitable for such administration. In his view the tendency to increase the number of people whose interests were associated with the State and to decrease the number who could bring to bear an independent view upon the activities of the State would threaten to disintegrate the best democracy.

Promotion for the Doctor

Dr. Hill confessed his belief that the best service was forthcoming with free choice and a system which rewarded those who rendered medical service in proportion to the services they rendered. This might be unacceptable doctrine to many, but with most the reward motive played an important part in their life and work. The man whose promotion lay with officials and committees tended insensibly to groom himself to catch their favour. He knew that it was said that the patient was incompetent to judge the technical value of the doctor's services, and that he might be influenced rather by sartorial than by scientific achievement. But the person who received care and treatment at the doctor's hands was better able to decide its value than the superior officer who made his judgment in the sterile atmosphere of the town hall. The bulk of the conditions which brought people to a doctor were not susceptible to the exact appraisement of the stethoscope or ophthalmoscope; they were due to poverty or frustration, to difficulties at work or at home, in fact to the social set-up, and only the doctor who looked upon the patient as a living unit in the community and dealt with him in a spirit of complete confidence could render him the necessary service.

What Might be Done

For twenty years or more the medical profession had been pleading for an extension of existing services, for bringing dependants into national health insurance, and for enlarging the scope of its benefits, but the appeal had fallen on deaf ears. There was need for the recasting of administration at the centre. The Ministry of Health was weighed down with non-health functions, and other health functions were distributed among half a dozen or more Government Departments; but there was no proposal on the Government side for comprehensiveness at the centre. What was wanted was a genuine central health department, with the Minister responsible to Parliament for the health services as a whole. Some new machinery was needed which would enable the administrator to combine with the doctor actually on the job. He believed that a corporate body such as the Unemployment Assistance Board or the War Damage Commission had much to recommend it. Into such a body not only administrators but men and women engaged in the actual job of medical work might be brought.

At the periphery there should be a recasting of the form and composition of local government bodies and of the areas over which they exercised authority. Under the Ministry's proposal the large authorities would group themselves to appoint representatives to a joint committee, but urban and rural district councils and borough councils would still be left with their environmental health functions, education committees would still be responsible for the school medical service, and mental hospital services—until the Minister changed his mind—were to have been left outside. The recasting of local government areas should have relation to areas convenient for hospital and medical services, and there should be on those bodies ample representatives of the people and voluntary bodies who actually did the job. This would take time—but it should come first.

He went on to speak of the voluntary hospitals, which, he said, were to receive some Beveridge and Treasury money but were to receive it through the grouped local authorities—that was to say, the proprietors of the municipal hospital system. That would lead to domination by the latter system, and it was not domination but partnership that was wanted. He deprecated leaving with any local authority the decision as to the bankruptcy or solvency of a voluntary hospital.

Removal of Barriers

"All that can be done at any one moment is to remove the economic barriers between the community and the services which exist. Beveridge does not increase the services, the Government in the House of Commons debate did not increase the services, the Ministry in its confidential discussions with us is not increasing the services. The removal of barriers, which is the immediate thing that can be done, could be immediately brought about by a two-way extension of existing national health insurance. I want to see an exhaustive independent inquiry into the administrative structure *before* a revolution is introduced into the methods of general and specialist practice."

Take the health centre, for example. To some people it appeared as a modern innovation, but in fact group medicine had made the voluntary hospitals what they were. The profession, he thought, wanted to see health centres tried out. It was not certain that in fact it would turn out to be an advantage to convert general medical practice into centre practice. Possibly there might be epidemiological disadvantages in the assembly in one building of a large collection of waiting patients. It was not settled whether the opinion of the profession was in favour of consultant and specialist diagnostic centres or communal surgeries, and it seemed fantastic to throw the organization of the profession upon a health-centre basis until at least one or two experimental centres had been tried out. During this period while the local government organization was being re-examined the support of the medical profession should be enlisted in trying out these centres and the methods of running them in different areas. There should be administrative as well as clinical experiment.

"We are ready," Dr. Hill said in conclusion, "to make available the existing facilities to all those who need them, and to extend those facilities. But we are not ready—and this is not the time to contemplate it—for a form of recasting in which the freedom of the profession would be exchanged for a form of civil or local government service. Quite frankly I do not think it is the time, when the most virile section of our community are away, to do anything more than remove any barriers which exist between the people and the existing services. It is not the time to develop a 'Socialist' cell within a 'Capitalist' organism. All I ask in the public interest is that the profession, which has done such good work on a basis of freedom, should not be converted into an ant-heap of organized mediocrity."

Discussion

The discussion was continued by Dr. E. E. LARKIN, who, as the occupant of a salaried post and also as a private practitioner, was able to speak of the advantages and drawbacks of both forms of employment. He distrusted bureaucratic interference with the work of doctors and gave some instances of the way in which the official mind tended to lose sight of human needs.

Dr. LETITIA FAIRFIELD said that a point which was sometimes overlooked was that from the patient's point of view a great deal of organization and planning was needed in order that the benefits of modern science might be brought to the community. Medical services had become so elaborate that the very wisest organization and distribution would not be possible if people were left to pay for medical services for themselves and their dependants. There was a great part of modern medicine which was much better done by whole-time officers than by part-time or by private individuals, but that was quite a different thing from taking into whole-time service an entire section of medicine which called for a different attitude on the part of doctor and patient. Here it seemed to her a question of further experiment by testing out the extension of the national health insurance system, and leaving practitioners with a certain independence even though part of their income was forthcoming from the State.

Among several other speakers in the discussion were Dr. MICHAEL SMYTH and Dr. H. B. MORGAN, M.P. The latter described the speeches from the platform as "High Toryism."

Dr. HILL, in reply, repeated that in his view there was room for change and for great improvement in the organization of medical practice, but the present was not the time, with the State encroachments on civil liberty which were necessary for war, to plan theoretical organization for the future. Rather was it a time to remove barriers which lent themselves to effectual removal without disturbance of the entire structure, and to encourage co-operation and partnership.

Nova et Vetera

A GUNSHOT WOUND IN 1814

Mr. W. S. EDMOND, F.R.C.S., of Shrewsbury writes:

At the Battle of the Nive, towards the end of the Peninsular War, Lieut.-Col. Tulloh, C.B., Royal Artillery, was severely wounded. The following account of his treatment, furnished to the Officer Commanding Royal Artillery under the Duke of Wellington, has recently been found among the papers now in the possession of the Royal Artillery Institution, and may, it is thought, be of some interest. Col. Tulloh's wound compelled him to leave the Army, for which he subsequently received a pension of £300 per annum.

Copy of the Staff Surgeon's Report

Toulouse 23rd May 1814.

I certify to have attended Lt.-Colonel Tulloh Royal Artillery from the 13th Dec. 1813 to the 25th March 1814 for a very severe gun shot wound received by him on the 13th Dec. 1813 in an action with the enemy near Bayonne.

The Ball entered the outer edge of the belly of the gastronamie muscles of the right leg, passed through the Tibia near to its head, where the texture is still spongy, & splintered it downwards without actually fracturing the bone, and was cut out on the inside of the shin. Some pieces of bone & gold lace came out with the ball, and he lost a good deal of blood.

For the first five days the local inflammation ran exceedingly high, & could only be kept down by the constant pouring of cold vinegar & water upon the parts; meanwhile that the orifices of the wound were covered with wax cloths to prevent their being irritated. The inflammatory diathesis excited in the general system was not strong, and only required the frequent use of cooling purgatives, salines, & other refrigerants.

On the 5th day the pain & irritation from the tension of the parts were great, but the strong action of the vesicles was beginning to subside & the wound began to suppurate—the cold applications were then changed for Fomentations, and poultices with great advantage & relief, which were continued for a long time to relax the parts in order to promote free discharge & loosen the splinters of bone & bring away extraneous substances which still remained in the wound.

From the *great* injury done to the bone in the first instance and the quantity of extraneous bodies as cloth, lace, and detached pieces of bone which were long retained in the wound by their getting entangled on the spiculated surface of the wounded Tibia & was a source of continual irritation; a high degree of inflammation took place, and extended itself along the front of the bone nearly as far as the ankle—various abscesses & sinusses formed—profuse & unhealthy suppuration ensued—the pain was *excruciating*, & the strong symptomatic irritative Fever which attended, reduced him to the *lowest state*.

For this the orifices of the wound were deeply and extensively dilated & various incisions made to prevent the extension of the matter by giving it a free outlet; the fomentations were continued—the bowels were kept regular by gentle warm aperients & glysters—the air of the chamber was kept fresh cool & *equitable*—his diet consisted of the most light & nourishing food—he was allowed porter & a certain quantity of wine so as not to heat him—and he took a mixture of Decoction of Columba, compound ʒss of Bark acidulated with sulphuric acid. and Laudanum in *large* doses at night.

By these means and as careful attendance as could be given him he recovered from this very dangerous state, & when I left him his general health was considerably improved—the extraneous bodies seemed to have all come away from the wound in the course of the ball excepting some small pieces of bone that remained yet firmly attached—but no Callus was thrown out to fill up the vacuity in the bone—and an extensive exfoliation was going on from the anterior part of the tibia which threatened to be a very tedious process, & to accelerate it he had begun to use the waters of the hot sulphureous spring at Cambo in the mode of topical bath, which seemed to be of some service.

He had the use of the knee joint, & could move the leg when in a horizontal position in bed, but had no other use of it, and it seemed doubtful whether he would ever recover the perfect use & former strength of the leg.

(Signed) JOHN MURRAY
Staff Surgeon.

More than a million dollars has been raised by the Canadian Aid to Russia Fund to provide medical and other supplies for Russian civilians.

BIRTHDAY MEDICAL HONOURS

The names of the following members of the medical profession were included in a Birthday Honours List published in *Supplements* to the *London Gazette* on June 2 and 4:

Baronetcy

Sir John Fraser, K.C.V.O., *M.C.*, M.D., Ch.M., F.R.C.S.Ed., Regius Professor of Clinical Surgery, Edinburgh University. Honorary Surgeon in Scotland to the King.

K.C.B. (Military Division)

Correspondence

Reaction to Typhus Vaccine

Sir,—It may interest some of your readers who are contemplating a course of typhus vaccine if I relate my personal experience following a second injection of Cox's typhus vaccine. The first injection of a second course (the first course of three injections was twelve months before and symptomless) had no local or constitutional reaction, and a week later I received the second injection—on Nov. 24, 1942, at 12.30 p.m. On the following day at 4.30 p.m. I experienced the most alarming symptoms, for, suddenly, while sitting down to tea, I became aware of a tachycardia, and a few moments later, without any impairment of reasoning power, I felt that my mind had left my body and I appeared to be looking down on myself sitting in a chair. I felt convinced that I was experiencing the transition stage between life and death. It was not until some months later, while relating this experience to a well-known epidemiologist, that I had my attention drawn to this state of dissociation as a symptom of typhus which was frequently referred to by Murcheson in his treatise on *Continued Fevers of Great Britain*, and recently described by Dr. Melville Mackenzie in the *Proceedings of the Royal Society of Medicine* (1941, Nov. 21, 35) as follows: "Dissociation delusions are often characteristic in the later stages of typhus. Thus the patient asks for his chin to be taken off for shaving, for his legs to be hung up at the foot of the bed or in the wardrobe, or he imagines that he has left a leg lying about downstairs." Dr. Mackenzie states that he has been so struck by this type of delusion that it may be of great value in the diagnosis of typhus in the second week of the disease.—I am, etc.,

Southampton. H. C. Maurice Williams.

Control of the Head Louse

Sir,—Dr. Gamlin's observations on the new methods of treatment for head lice deserve careful attention. Some of his conclusions are, I believe, unjustified, but all are significant.

The lethane hair oil has been investigated in many centres by a great number of doctors and nurses, the almost unanimous opinion being that it is better than others hitherto used, both on grounds of efficiency and convenience. This was a judgment of comparison: as regards absolute effectiveness there was a considerable difference of opinion. The figures that Dr. Gamlin quotes (0.916% to 35% failures) are the extremes of the range of variation. I believe that this difference of absolute values depends on the relative efficiency of the operators in two respects—viz., thoroughness of application and care in examination for surviving larvae. Dr. Gamlin rightly describes the way in which a few small larvae can be overlooked. As regards efficiency of treatment, this mainly depends on the amount applied, which is difficult to standardize owing to variations in the amount of hair.

The statement that thiocyanates kill nits is called into question, so that I would like to quote laboratory data proving that this is true. By lightly spraying lice or nits with solutions of various insecticides it is possible to determine the amounts necessary to kill 50 or 100%. Figures for the substances in question are as follows:

	Amount (mg./sq. cm.) to give a complete kill of:	
	Lice	Nits
A. β-butoxy-β'-thiocyanodiethyl ether	0.027	0.036
B. Thiocyanethyl laurate	0.090	(Not determined)
C. Lauryl thiocyanate	0.077	0.186

(N.B.—Lethane hair oil contains 6.25% A and 18.25% B.)

It is clear that minute quantities of thiocyanate are lethal to louse eggs. Failure to obtain a complete kill in practice must be due to the difficulty in wetting every nit on an infested head with a small quantity of fluid.

The volatile principle in "lethane 384 special" which Dr. Gamlin mentions is the β-butoxy-β'-thiocyanodiethyl ether. The other ingredients (thiocyanethyl laurate and lauryl thiocyanate) are scarcely volatile (vapour pressures similar to that of mercury). Much oily material can be drained out of a head by contact with pillows and hats.

In the original paper by Prof. Buxton and myself (*Journal*, 1942, **1**, 464) we stated that the insecticide should not be distributed by combing. That has sometimes been misread as a positive injunction not to use steel combs. Removal of nits may be desirable for several reasons—e.g., aesthetic, to reassure patients or parents, or to differentiate new infestations. Fine combing can easily be combined with the lethane treatment by applying the oil after combing, if conscientious nurses or orderlies can give the time. But lethane treatment alone will probably be more readily used by many infested persons not under discipline or compulsion. In our experiments Buxton and I obtained about 95% success with one treatment only. Two treatments spaced a week apart should give a vanishing proportion of failures.—I am, etc.,

J. R. BUSVINE.

Psychiatric Treatment in General Hospitals

SIR,—The admirable facilities described by Dr. Dalton Sands (May 22, p. 628) as obtaining at the Sutton Emergency Hospital, and advocated in your leader as measures meriting wider application in post-war reconstruction, nevertheless constitute no real advance upon those obtainable in the best examples of the public mental hospitals to-day. That this should be the case is not surprising, since it was by the adoption of methods already proved in the modern mental hospitals that those of Sutton and similar emergency hospitals were derived. The alleged advantage of the general hospital as against the mental hospital is, in fact, reducible solely to the matter of "stigma," from which it is argued that the former are free. Now this plausible suggestion upon examination has been found to be invalid, since precisely the same stigma we know speedily becomes attached to the "mental ward" of the general hospital; this, we would add, is not surmise, but actual knowledge which could be exemplified and independently attested. To suppose that the substitution of the word "neuropsychiatric" for "mental" will change the connotation is to underestimate the powers of public discernment. To attempt to relegate the mental hospitals proper to their former melancholy role of custodianship largely of the chronic incurable (our diminishing heritage of pre-therapeutic days) not only would be a poor return to those who have initiated and evolved those therapies, which Dr. Sands now seemingly wishes to appropriate for more particular use elsewhere, but would be a public disservice, since, if implemented, it would deprive the mental hospitals of opportunities for further advances, because potential recoverability is here an indispensable prerequisite. Fortunately, the public have already become aware of the merits of, and facilities offered by, the mental hospitals of to-day, and the success of the voluntary system testifies that the bogy of "stigma" is a rapidly diminishing deterrent.

The following statistics refer to the Warlingham Park Hospital, which is the mental hospital for the County Borough of Croydon, and serves a population of approximately 240,000:

Year	Total Number of Direct Admissions			
	Certified	Temporary	Voluntary	Total
1932	119	0	6	125
1942	40	12	225	277

They demonstrate clearly that there has been a revolution in the mode of admission duing the last decade. The great increase in the number of admissions is not attributable to any increase in the incidence of mental illness, but to the rapidly diminishing prejudice against mental hospitals, resulting in large numbers of psychoneurotics as well as psychotics seeking admission. They also demonstrate how the number of patients needing certification in an area can be materially reduced when full use is made of the provisions of the Mental Treatment Act, combined with active therapeutic procedures.

Dr. Sands's figures regarding the financial advantages of neuropsychiatric units are particularly misleading. They are based on the assumption that his patients would have been untreated and become chronics had they been admitted to mental hospitals. On the contrary, there are many county and county borough mental hospitals where exactly the same facilities for treatment are available to the patients as obtain at the Sutton Emergency Hospital, at a cost to the ratepayers of below 35s. a week, which is less than half the sum he mentions as the cost of their treatment in a general hospital.

While we recognize the desirability of having mental wards or blocks attached to the great teaching hospitals, we are of the opinion that the mental health of the community will be best served not by setting up new centres of treatment and calling them neuropsychiatric units but by concentrating attention on the already existing mental hospital, and would urge that the first change called for is a substantial increase in the numbers of both the medical and the nursing staffs of the mental hospitals. Such changes, combined with the full utilization of the provisions of the Mental Treatment Act, would transform our hospitals, and incidentally might prove that the "chronic insane" are not so chronic after all.—We are, etc.,

T. PERCY REES.
W. H. SHEPLEY.

Warlingham Park Hospital, Surrey.

SIR,—Dr. Dalton Sands's article (May 22, p. 628) on the treatment of psychiatric patients in general hospitals marks a distinct advance in the approach to the extensive psychiatric problem, and I suggest that he send, with his compliments, a reprint to the Board of Control, so that the matter may be brought officially to their notice. It is true that Dr. Sands's cases were carefully selected. But, in view of the control possible by modern methods of treatment, the time has clearly come when all large general hospitals should have a neuropsychiatric ward or unit to which every clinical type of psychiatric disorder could be admitted.—I am, etc.,

London, W 1

FREDERICK DILLON.

Slow Union of Fractures

SIR,—As a general surgeon I approach the subject of slow union of fractures with trepidation and due humility. However, my experience of fractures dates from before the last war and, of late years, has been extensive. Certain aspects of the problem have not had the attention they deserve. Causes of slow union may be classified as constitutional and local. In these days stress is laid on the latter to the exclusion of the former. Experts have, quite rightly, broadcast the importance of accurate reduction and adequate immobilization. My object in writing this letter is to bring forward the suggestion that there is a specific constitutional factor, peculiar to the individual, which is responsible for callus formation. How, otherwise, can one account for the great variation in time taken to obtain union in similar fractures in patients of similar type? Again, in some patients muscle may lie between the bone ends and yet union will take place by means of a bridge of bone over the muscle.

I have formed the impression, difficult to substantiate, that union is delayed when fractures are multiple—as if the callus-forming capacity of the body is limited. Among the large number of fractures that I have treated the few that have required a bone graft have been in apparently fit, muscular men. Shaft fractures in the aged and frail usually unite without trouble. I have treated a number of fractured femurs in which the bone has been affected by osteitis deformans. Even when reduction has been imperfect union has been rapid and accompanied by abundant callus formation. In these disjointed observations may lie the clue to the problem. The biochemist who can solve it will do a service to humanity. In conclusion I will quote one case.

A soldier 21 years of age sustained a closed fracture of the femur and an open fracture of the leg bones. About two inches of the middle of the shaft of the tibia was comminuted into three fragments, each, apparently, detached from any blood supply. I removed one fragment and wedged the other two into position as grafts. The limb was encased in plaster and slung on a bent Thomas splint, with moderate skeletal traction to femur and leg bones. The outlook seemed to be bad: there were multiple fractures and one was compound; union in fractures below the middle of the tibia is notoriously slow; the loose fragments were avascular. Yet note the result. In six weeks the femur appeared to be firmly united. In twelve weeks a mass of callus united the tibial fragments, and the patient was able to get about with the aid of a calliper. Surely this patient was lavishly endowed by Nature with the specific factor which I venture to postulate.

—I am, etc.,

Northampton C. C. HOLMAN.

Night-vision Tests

SIR,—The papers on testing night vision by Dr. K. J. W. Craik and by Dr. John Yudkin and Mr. Andrew Ferguson in your issue of May 22 are without doubt of great interest. But there are certain points which these writers and investigators overlook—at least, according to my reaction to eye work of such a type. These three writers are research workers of distinction. The work they do and can do is impressive; but it is wholly or mainly associated with first-class laboratories, where equipment is as perfect as it can be and where exceptional construction can be carried out by technicians. In their criticism of my disk-spotting night-vision test they write wholly from the point of view of the laboratory; whereas I, in relating my experiments and observations on night-vision testing, took my impressions and made my arrangements as a worker now cut off from all laboratories and alone, in a position similar to that of the majority of ophthalmic medical practitioners. I had evidence of other tests being made, and was sure that these tests, however perfect they might be in theory and in the care given to their make-up, were not tests that independent and solitary eye-men could get or could make use of effectively. So my test was designed to meet solitary needs, and from the personal evidence of colleagues it appears to meet those needs.

In my papers on the disk-spotting test I made it plain what was the basis of the test It was a simple imitation of what we see in the sky on a clear night—spots of light-stars. Folk with good sight and good night vision can see and count stars with amazing accuracy. Some stars shine with their own light, and planets reflect the hidden sunshine. The disk-spotting test is an imitation of the latter. The candle in its box shines on the white disks, which reflect the light. The distance at which the folk could see and count the disks showed their measure of night vision. Children said the disks were stars! And the reaction of interest to the test by men, women, and children, and by colleagues, showed that it is attractive; and a test that has an attraction generally gets the best reaction Further, I have shown how easily the lighting can be varied to test those who are suspected of shamming night-blindness.

The next point I had in mind in designing this test was to make it so simple that anyone, anywhere, could make it for himself and obtain a reasonably accurate reaction The first test I made myself. It worked well. The description given of the test is such that I am sure any eye-man could make one for himself if he were unable to get one from the London makers. That, I maintain, is a point of high value in comparison with the elaborate tests designed in the research laboratories. These cannot be made except by expert technicians.

Certain criticisms are made by these three writers on the use of the disk-spotting test. Rightly it is said that the disks vary in size to the eye of the subject according to the distance at which he stands That is true. I found no disadvantage in that. People with poor night vision go closer up, where the disks are larger and easier to see; they get some reaction. The keen-sighted folk go further back, where the disks are smaller and harder to see: the returns by young people who could count at 8 metres are amazingly good.

The critics state their dislike of the use of the "standard candle." To most of us who have electricity the candle is an ancient light. But when the electricity is off, the candle is precious even to-day. The variation of the "candle power" shown in the use of a candle by the critics amazes me. It is evident that they did not take any steps to adjust the working of the candle. My candles behaved well, and I always had a means of accurately, quickly, and easily checking their burning, and without looking at them. The candle was lighted and put into position, and shone on the disks for 15 minutes. Then I could always count the disks myself at the distance of 5 metres. If at any time during a series of tests the light varied so that I could not count at 5 metres or could count further away, then I knew the candle was burning poorly, and I duly adjusted it, wearing dark glasses. Also, I never used a candle for more than one hour; it was then discarded. I think all eye-men would use the candle in this way, for we are always watching the test submitted to the patient.

I have used this test in five different sorts of places—a corridor, large rooms, a big hall, an Army Nissen hut, and at my home. In each it worked well. It is of light weight, easily carried, and independent of any wired connexions. So it may be of use in conditions that demand an easy and convenient night-vision test. The charts of the reactions of groups of subjects of different ages seem to me to be reasonable evidence of its effectiveness in classifying individuals.

Regarding the time of adaptation to the darkness, I found 15 minutes generally useful. But anyone who failed to pass the test reasonably at the distance of 5 metres was given a double time—sometimes, when the person desired it, even more. But cases that showed a gain by such extra time were very few. All my folk were well fed.

—I am, etc.,

An Unusual Retrocorneal Phenomenon

SIR,—Dr. H. M. Tietze's report (May 29, p. 665) of a globule of vaseline floating in the anterior chamber is very interesting and must be very rare. His citation reminds me of a case (first seen at Newcastle by Mr. Arkle) in which a spicule of glass remained free in the aqueous for many months. In the erect position it disappeared, and could be seen only when the subject was directing his gaze downwards: in this position it could be detected in the corneal concavity. Symptoms of irritation (probably endothelial) indicated operation. This necessitated an incision in the periphery of the cornea, with the patient lying on his front, his head protruding over the end of the table, and the eyes turned downwards. The aqueous being released, the glass spicule was found in the wound and easily removed. The eye retained useful vision, and the attacks of irritation ceased (see *Trans. Ophthal. Soc. U.K.*, 1930, **50,** 118).—I am, etc.,

London, W 1 F. A. JULER.

Treatment with Tuberculin

SIR,—Dr. H. V. Morlock and Dr. N. L. Rusby (May 22, p. 648) confirm the timely warnings regarding "ambulant" A.P. treatment which have been appearing in your correspondence columns lately, and rightly state that the cure of phthisis can only be attained by the patient developing resistance to the disease by the measures embodying the "sanatorium routine." Yet, failing actual residence in a sanatorium owing to shortage of accommodation—the point which originated the correspondence under the above heading—there is a remedy that acts by raising and developing the patient's natural resistance—namely, tuberculin. The successful clinical application of this property of the drug requires fine appreciation and judgment of the degree and variations of the natural resistance of each individual patient—a difficult art, which seemed to have been acquired by a few tuberculosis clinicians in the years immediately preceding the last war. Since that event, and apparently largely for reasons directly and indirectly consequent on it, the use of tuberculin has practically died out.

In the sanatorium in which I was a patient, and later A.M.O., some thirty years ago, the majority of patients in the earlier stages of the disease were given tuberculin, and from correspondence my wife and I have kept up, since I gather that quite a number of my fellow patients are still alive, well, and working—a number considerably in excess of the statistical figures relating to the expectation of life for consumptives. Others, it appears, remained well until carried off in the course of time by other illnesses. Some of us had prior courses of autogenous vaccines with the object of reducing mixed infection, a procedure which in my case was very successful. Tuberculin was not given to cases with pyrexia unless it became reduced to a low degree by this means, or by "typhoid" rest. It was not withheld from apyrexial laryngeal cases.

Looking back on twenty-five years' clinical tuberculosis work, and as the result of my experience of their administration to and by myself and others, I believe that tuberculin and autogenous vaccines would be the most generally applicable and successful specific means of therapy alternative to sanatorium treatment. The ideal, of course, would be to inaugurate it while in sanatorium residence and continue it under the environmental conditions in which the patient is to live and work.—I am, etc.,

Old Colwyn. W. B. MARTIN.

Diet and Insulin in Diabetes

SIR,—The articles by Dr. Micks (May 15, p. 598) and Dr. Crooke (Jan. 16, p. 64) on the diet in diabetes have certainly caused a great deal of disturbance in people's minds who think that a scientifically worked out diet with an appropriate amount of insulin is always required to keep our diabetic patients under control. Though an imaginative and intelligent patient will learn to eat the required calories of each foodstuff, the less gifted and more casual diabetic will frequently follow a less arduous routine and may keep quite well on it so long as he takes sufficient insulin to prevent ketosis. There must be many who will have observed this in their daily practice, and Dr. Micks and Dr. Crooke have made public some facts which really were common knowledge but were against the scientific teaching on the diet of diabetes.

One frequently sees patients who have been stabilized on a carefully controlled diet and a certain amount of insulin and who religiously continued with this treatment over a number of years. They were periodically seen, and as they appeared to be well were advised to carry on. I have met a number of patients recently who were kept on 40 to 60 units of insulin daily for ten years or longer. They were admitted to hospital, and it was found that they could be kept stabilized on a very much smaller daily dose of insulin. Some required no more insulin, and a calorie control diet was found satisfactory in all cases. There must be many diabetics whose insulin requirements have become less but who are still continuing on their original diet and insulin doses.—I am, etc.,

Essex County Hospital, Wanstead. E. FRANKEL.

Treatment of Blackwater Fever

SIR,—A few years ago, before I had to cease practising in East Africa owing to an accident, I found that 8 to 10 gr. of sodium luminal (the soluble salt) intramuscularly cured blackwater fever at once. On leaving East Africa I asked my partner, Dr. J. R. Gregory of Nairobi, to continue this treatment and to let me know his results. He has written me recently that he has had a series of thirty cases, all of which he cured at once by giving each an intravenous injection of 1.5 gr. of phenobarbitone. He also mentions that Dr. D'Souza of Nairobi, whom he had told of this treatment, has had similar success with it.

I had always been struck with the great restlessness of mind and body in this illness in all races, and I reasoned with myself that if I could counteract these symptoms I should be master of the situation. Thirty years ago I used to give morphine for this restlessness, but I was never satisfied that it did any lasting good. Seeing that blackwater fever is now likely to be commonly met with by our medical officers in the Forces I think this treatment might be made known. I would have brought it to your notice before, but I have been laid aside since coming home.

In my series of eight cases the injection was given immediately on my seeing the patients about 7 p.m. At 10 a.m. next day, when I next saw them, there was no trace of blackwater fever. Of course they were given drinks of a solution of sodium bicarb. and glucose (or sugar); they were wakened during the night to be given these drinks. I had not to give any more luminal after the first injection; there were no recurrences.

Dr. Gregory has had the same experience in all his cases. He suggests that the luminal in this treatment may act in other ways than by doing away with restlessness. He has reasons for thinking so. When I hear from him again on the subject I shall let you know.

I have used the unscientific expression "cured at once" for the express purpose that it gives the picture exactly. I have had a life's experience in the treatment of blackwater fever and have tried every conceivable method and experiment, but I have never been even temporarily satisfied that I had found a cure until I hit on luminal. Vomiting and diarrhoea are common in this state; hence the necessity for giving the drug by injection.—I am, etc.,

Ballycastle, Co. Antrim. R. W. BURKITT.

Diagnostic "Tricks" for Pleurisy and Peritonitis

SIR,—The interesting diagnostic trick given by Dr. Stanley C. Raw (May 22, p. 648) prompts yet two others. There is a well-established central inhibition of respiration which occurs during swallowing, in order to prevent food particles being drawn by the ingoing current of air into the bronchi and lungs. This inhibition of respiration on swallowing a bolus of food or a mouthful of saliva lasts for five or six seconds. If the rigidity of the upper half of the abdominal wall is due to pleurisy, relaxation occurs during this period; if due to peritonitis, the rigidity is unchanged. Yet again, flexion of the head and neck on the trunk, as in looking at one's feet, produces contraction of the upper half of the rectus sheath. During such a movement the pain of pleurisy is not sharply increased, that of peritonitis is.—I am, etc.,

Anatomy School, Cambridge. H. A. HARRIS.

Pain and Cancer

SIR,—The late Lord Moynihan was lecturing to a lay audience on cancer and was pleading for the early case: "Get the case to the surgeon early and cures can be effected." One insignificant man in the back of the audience got up and asked, "How are we to know when we have got early cancer?" The peer was nonplussed. I am about to start some work on the signs and symptoms of early cancer, and appeal to readers for criticism of the following observations; they do not pretend to be facts but are impressions I have formed.

Much is being spent on discovering a cure for cancer. I submit that, while no one could consider the knife to be the ideal weapon, in the present state of our knowledge, or rather ignorance, of cancer, it offers the best prospect for internal cancer—excluding that of the mouth and uterus, which respond so well to radium. But for operative success the case must be seen early, so it would appear to be most profitable to discover what are the signs and symptoms of the early case.

Pain is the commonest symptom for which medical advice is sought; it is one of the blessings man is heir to, since it directs attention to dysfunction. Just as the first thing a gardener does before pruning a tree is to cut out the dead wood, so in the approach to early cancer we must cut away all useless signs, chief of which is pain. Cancer is essentially painless in itself, it destroys nerves without stimulating them painfully. The lay public think cancer is painful from the start; nothing could be further from the truth; many cases, they would be surprised to know, run their course painlessly. Particularly is this so in gastric cancer, the disease pursuing its inexorable course till the end, which would appear to be like a Buddhist's haven.

The causes of pain in cancer would appear to be:

(1) *Secondary Infection.*—This is the rule in cancer of the lip and mouth; also of the breast.

(2) *Occlusion of the Lumen of a Hollow Organ.*—The stomach provides a good example of this; while the more usual is a painless malignant ulcer, less commonly a cauliflower growth, causing an *x*-ray filling defect, occurs; this occludes the lumen with the production of pain, which focuses attention to the stomach, which can be dealt with surgically. Cancer of the rectum impinges on the lumen of the gut late in the disease and so is painless until inoperable, when agonizing pain may develop. Pain localized to a definite point in

the course of the transverse or descending colon is a valuable symptom of a "ring" carcinoma. A hypernephroma may be palpable in the loin or cause painless haematuria long before it occasions pain, when this is due to clots or pieces of growth. Cancer of the bladder is painful only when it obstructs the ureters or urethra. A bronchial carcinoma gives rise to pain when it obstructs the bronchus. Headache, vomiting, and optic neuritis were the triad of symptoms on which cerebral tumour used to be diagnosed; the headache was due to disturbance in the circulation of the cerebrospinal fluid. Uterine cancer sets up pain when it occludes the lumen.

(3) *The Formation of Adhesions.*—By this not very fortunate term I mean the prolongations and secondary fibrosis which accompany a spreading cancer; it is best seen in the breast. At the outset there may be some discomfort as the breast is pendulous and the tumour has a tendency to congestion. Soon, however, it spreads along the fibrous tissue of the breast and becomes, as Mr. Sampson Handley has pointed out, palpable to the flat of the hand; previously it was only palpable to the fingers. At this stage the cancer becomes somewhat painful but by no means so painful as many cases of interstitial mastitis.

—I am, etc.,

London, W.1. A. P. Bertwistle.

Coarctation

Sir,—Dr. H. S. Gaskell's criticism (April 3, p. 426) of the diagnosis in Dr. C. W. Walker's case of labour associated with congenital coarctation of the aorta contains so much that is inaccurate and obsolete as to call for comment. The view that necropsy is necessary to demonstrate the enlarged collateral vessels developed in coarctation is entirely out of date. Boyd, in his *Pathology of Internal Diseases*, explicitly states that the condition is diagnosable during life, and adds that the diagnosis is often not only possible but easy. Enlarged vessels along the dorsal border of the scapula may show pulsation not only palpable but visible. Characteristic crenations of the ribs produced by dilated mammaries and intercostals are demonstrable by x rays.

The stenosis in coarctation is not necessarily confined to the "isthmus." It can occur at the insertion of the ductus or below it. The left subclavian artery does not come off the aorta below the ductus, as stated by Dr. Gaskell, but above or proximal to it. Even a misapprehension as to the origin of the left subclavian, however, can hardly explain the extraordinary statement: "Common sense would seem to dictate that the blood pressure distal to the constriction would be low whereas a hyperpiesis is present." Common sense and an appreciation of physical principles would surely indicate a high pressure proximal as well as a low pressure distal to the constriction—i.e., the precise findings reported by Dr. Walker. Even in the rare cases where the constriction is proximal to the left subclavian there is a hyperpiesis in the right arm.

The view that the murmur described is the only item in favour of the diagnosis is more extraordinary still when one considers that high brachial and low femoral pressures, marked arterial pulsation in the proximal and collateral vessels, diminished or absent femoral pulsation, and cardiac enlargement are not only to be expected on theoretical grounds but are referred to in practically any modern textbook dealing with the subject. Incidentally coarctation is now regarded as more common than was formerly thought, and examination of the femoral pulse is advised in all cases of high blood pressure when first discovered.—I am, etc.,

Killygordon, Co Donegal. John G. O'Brien.

Multiple Muscle Herniae

Sir,—It was interesting to read the article on this subject (May 15, p. 602), because two years ago I came across some cases identical with those described, save that there were only two or three such muscle herniae. They were in infantrymen, who had recently had strenuous physical training and marching, and who were complaining of pain and aching after marching and drill. I operated on one to see whether anything could be done, but found the whole of the muscle sheath in that area was very thin and friable and the stitches mostly cut out. A darning suture, however, was done, and on discharge from St. Michael's Hospital after a short period of walking they had not recurred. Whether they did later I do not know as the patient went away from this area.—I am, etc.,

Hayle, Cornwall. W. H. Palmer.

Medicine and Politics

Sir,—Dr. Geoffrey Bourne, in two articles in your columns, has entered the field of politics which he otherwise so much despises. To him, apparently, everything is either good or bad, black or white, democratic or bureaucratic, political or scientific. However, reality is not a bit like that, and, despite his assertions, local government is not so black nor are voluntary hospitals so democratic as he depicts them. Local government is essentially a democratic institution, but the apathy of the electorate, the development of multiple authorities, the irregular size of the areas controlled and their historically developed peculiarities, forms of administration too rapidly outgrown—all call for a reform which cannot be postponed merely because solution is difficult. It is not surprising, therefore, that their hospitals have suffered. On the other hand, the voluntary hospitals have demonstrated the advantages of decentralized management, but they are not democratic in the sense that their management committees only represent the subscribers of about 30% of their total income. It must be remembered, too, that a medical service is not solely staffed by doctors; and nurses, for example, find no democracy *for them* in either type of hospital, though some local government hospitals are enlightened enough to grant a 96-hour fortnight, the right to live out and to get married, and an entrance into the service without an inquiry into social background.

Dr. Bourne is equally wrong when he contrasts politicians and doctors. We are all politicians, we all have a vote, can be members of political parties, argue in pubs or clubs, oppose progress or promote it, and write letters to the *Times* or the *Daily Worker*. Those who are elected by the people vary in their knowledge of history, government, and economics as much as doctors vary in their knowledge of science, despite the latter being qualified.

However, let us listen to Dr. Bourne: "History proves that scientific freedom and research are of vastly greater importance to humanity than administration." I suppose that this means that Dr. Bourne can prove from history that, etc.; but can he? How does he define scientific freedom, and, more important to us at this moment, how does he define medical and professional freedom? Is it the freedom to practise medicine in an unchanging way in a changing world; the freedom to treat rheumatism with salicylates instead of preventing it by rehousing; the freedom to prescribe bromides to those whose sufferings are psychogenic; the freedom to isolate the illness from the patient in his environment?

No, Dr. Bourne, it is not, for medicine is a social function, and the doctor's freedom is the freedom to serve man as he lives in society, and this cannot be done by groups of doctors sitting by themselves round a table, nor by research workers selecting subjects in "pure" medicine to contemplate in an ill-financed laboratory in disregard of the needs of the public. And then, if a neglected but conscious public starts consciously to plan for its needs, will we really lose our intellectual freedom if we help them?

Dr. Bourne, however, prefers the idea of doctors controlling themselves in splendid isolation to working in co-operation with the rest of society, because he is unable to see the alternative. He cannot imagine that the people and the doctors can work together without producing a rigid machine; he cannot see that the people and the doctors together can produce a living organization, and can devise forms that will enable a comprehensive health service to come into being which will preserve initiative and preserve the doctors' role of advising the public. Many things must be reconstructed after this war, and the public might well expect the doctors to take a part. Dr. Bourne prefers to pass pious resolutions: "Medicine and science must not be political"; I need add nothing to such a political statement.—I am, etc.,

London, W.1 Hugh Gainsborough.

Sir,—Now that you have opened your columns to political propaganda I do hope that we can all arrive at some clearer understanding of what we mean by politics. I myself cannot conceive of any definition that does not entail medical science being closely linked with political activity—acknowledge it or not as you will.

Dr. Geoffrey Bourne's article will confuse any genuine student. For instance, consider "a national comprehensive medical service"—this is obviously a political matter on any definition. Does Dr. Bourne suggest seriously that doctors should not concern themselves or medical science is not concerned? It is quite possible and desirable that a political programme should feature medical research and scientific freedom prominently. It is quite impossible to do research or practise any science *in vacuo*. Stagnation and death inevitably follow even tendencies in that direction. Somewhere and sometime the research worker must relate himself to the society he works in, and he must enter the political field, either personally or through contacts.—I am, etc.,

TOM GARLAND.

*** We fail to understand the meaning of Dr. Garland's opening sentence. It has for some time been the custom of the *B.M.J.* to report activities of the Socialist Medical Association, of which Dr. Garland is a member.—ED., *B.M.J.*

State Control of the Medical Profession

SIR,—I think that it is important to analyse what is meant by the "State," for one is apt to look upon that word as symbolic of some super-power. Presumably it means, in effect, "Parliament," and we must attempt to analyse Parliament. This body contains a certain group of wise, and sometimes great, men and women, a large group of intelligent and sub-intelligent worldly-wise men and women, and a modicum of the ever-present "climbers" who will sacrifice all and anyone to achieve personal success, and of fanatics. No one doubts fanatics have done great things, but in a stable institution in an old country they are generally dangerous. The success of Parliament can be seen in two terrible wars in which our bravest, most honest, and truest have been sacrificed, and in the efforts of members to advance their political creeds when our country and empire are fighting for dear life and freedom.

If our great profession—and it is a very great profession—thinks it wise to put itself completely into the hands of this "State," I think all should recognize that, once done, there will be no escape. The profession will not be bound in chains but enclosed in an impenetrable net of steel from which no escape is possible, but the strength of the steel steadily increases. Naturally there is diversity of opinion on State control, but there can be little doubt as to what this implies in the great cry for freedom we hear on all sides: slavery for a great profession.—I am, etc.,

Bath F. JOHN POYNTON.

Doctors and the Future

SIR,—The seven signatories from Bournemouth (May 22, p. 649) did well to pose their question. Is anything, they ask, really seriously wrong with our profession, and, if so, cannot something radical be done about it? They are even prepared, if the worst came to the worst, to consider "a panacea envisaged by idealists." Let them, anyhow, listen to the following.

Whoever wants to understand the real problems that beset the medical art at present must imperatively study them in connexion with what is going on in the State as a whole. The present holders of power in this country, basing themselves on the usual assumption that competition is the law of life, intend to make post-war Britain (or quite possibly Britain-America) the biggest "business" in the world, able to defy all competitors. To this end "our country" must obviously be mechanized through and through, turned into an industrial machine, and the vast majority of its inhabitants made either cogs in that machine or, at best, machine-tenders. The scheme indeed is already working in its early stages, and arrangements are being made that the medical profession shall progressively be enlisted to help in procuring the smoothest possible running of the works. In other words, the future role assigned to the doctor will be that of a "machine-minder." He is already becoming so, as witness the almost automatic and predominantly clerical duties which he is at present called upon to perform; to many a medical man, "signing lines" is now almost the chief business of his day.

To what I have said, however, quite a number of people will probably reply, "Well, if the doctor is properly paid for this, and if the work 'needs' to be done, why should he not do it?" My answer is that man is not, by his nature, a machine, and that therefore a persistent effort to mechanize the bulk of people will finally so violate their natures as to provoke terrible social convulsions. The present plan is not going to work, and practising doctors are infinitely better qualified than politicians to think out one that will. In any case, I have mentioned the essential preliminary considerations. What is happening in medicine is merely a symptom of a disease in a wider field, and doctors, above all people, should know that when a disease does not cure itself it must be tackled as a whole and not symptom by symptom. Let the members of our profession gird up their loins and become medico-sociologists.—I am, etc.,

North Queensferry, Fife. A. J. BROCK.

SIR,—Is it not a fact the dissatisfaction felt both by public and medical men alike with the present system of medical practice can be completely removed by three (relatively) simple measures?—the inclusion of the dependants of "panel" patients in the National Health Insurance scheme; the provision of wider consultation and laboratory facilities for these patients; and the institution of some form of insurance (on the lines of the Oxford Provident) to guard the "middle-class" patient against the disastrous expense of surgical operations and the like.

These three steps having been taken, would not any totalitarian system of State medicine appear to be ill timed, because of the years of crisis through which we are passing and have to pass; impractical, because of the vast expenditure involved at a time when economy will be the nation's imperative need; and ill conceived, because such a system must inevitably be negatived by the weight of stultifying bureaucratic control to which it would be subject? And, finally, are not your correspondents from Bournemouth, in the issue of May 22, to be congratulated on knocking the first piece of stuffing out of a singularly unconvincing medical "scaredoctor"?—I am, etc.,

Harrogate. FALKLAND L. CARY.

The Government's Proposals

SIR,—The Beveridge report provides for an increase of sick benefits, to qualify for which a medical certificate will be necessary. Sir William knows only too well that the whole scheme will collapse if the patient continues to receive the benefit of the doubt, as he always does and as he should always do. He will always receive it so long as his doctor remains his friend.

It is vain to argue about the precise form of control we are prepared to accept. Free treatment for all means a machine to work it, and that machine must be staffed and the financial control must be lay, and whoever controls the money will control the profession. We now see clearly the imperative need to kill private practice and to degrade a great profession. Starting with a comprehensive service and increased benefits, a free profession at once is encountered as a fatal obstacle. To a truly democratic mind a free profession would be axiomatic; to the modern planner it becomes quite clear that it must be liquidated. Safe with a salary the medical man of the future, recruited from the safety first section of the young, will have no difficulty in deciding that it is better to please his employers than to please his patients, and the funds will remain solvent.

Movement is not necessarily progress. We took a wrong step long ago when we consented to feed the hungry sheep with certificates. It has turned out rather badly, and the suggested remedy is a great new step in the same direction. Perhaps it would be wiser to halt awhile and consider whether we should not move back a bit. We shall produce only despair if we persist in supposing that the great evils from which humanity has so long suffered can be cured by a cash payment.—I am, etc.,

Hendon, N.W.4. R. W. COCKSHUT.

SIR,—I have talked with several general practitioners in this district and find that they are all in agreement with what Dr. Samuel Grasse states (May 29, p. 679). The only thing that we dislike about the proposals of the Government is the administration of the scheme by the local authority.

The things which I find we all want are: (1) compensation for loss of practice; (2) an adequate salary based on the Government's proposal (previous service to be taken into account for seniority and salary); (3) all expenses paid; (4) one month's holiday with pay per annum; (5) a fortnight's study leave per annum; (6) a pension of two-thirds of the retiring salary at the age of 60; (7) a rota of duty so that the practitioner is not on duty for 24 hours a day and has the chance of an occasional week-end to himself.

As Dr. Grasse says: "Let a plebiscite be taken from the profession on the particular and specific issues involved." I find that there is absolutely no desire among the practitioners with whom I have discussed the matter to have an extension of the panel system with its inadequate remuneration, long hours of arduous work, and iniquitous competition.—I am, etc.,

Doncaster. H. M. BROWN.

SIR,—It is heartening to general practitioners, overworked and withal a little tired, to see signs of a general rebellion against a new planning of medical practice and the regimentation of medical men. It is heartening to know that some are daring to say that from the point of view of the general public the profession is the best organized in the country. Few organizations composed of free-acting individuals could work in fuller harmony with each other and the public they serve. The public realize the general efficiency of the organization, and their remarks on State interference on a broad scale are mostly unprintable.

The principles of this service to the public have been evolved by the profession and through its own initiative. Over and over again it has had to find the material with which to make its own bricks. The general public and notable individuals have not been backward in finding that material, and rapid progress has been maintained. The profession and the public are inseparably linked up, each a little jealous of the satisfaction of giving to the other of their best, and the intrusion of a third party—the State—with its infinite capacity for the destruction of initiative and gallant individual enterprise, will not be acceptable to any but the misfits on either side.

The Ministry weaken their case with the call of "urgency." There is no urgency except for them. Thousands of medical men are solely occupied with their Service duties and commitments, and those at home are dealing, not unsuccessfully but at the expense of much overtime, with the civil population. The Ministry must be aware that their chances of "planning" the profession will be slender indeed if they wait until normal, or comparatively normal, conditions return.

Let us be told simply what reforms the Ministry consider necessary, but let us see to it that they listen closely to those reforms that we consider necessary and help us to their attainment. We will willingly accept their help, but they will be unacceptable as senior partners. Their influence is too deadening for the progress which is rapid now and will be far more rapid after the war, and whose aim is the maintenance of health and the war against disease.—I am, etc.,

Kineton, Warwick C. J. L. WELLS.

Obituary

FREDERICK GYMER PARSONS, D.Sc., F.R.C.S., F.S.A.

Prof. F. G. Parsons will be remembered by a long succession of former medical students of St. Thomas's Hospital as an able teacher who knew how to make all things seem simple. He was appointed lecturer in anatomy in 1886, and was professor of anatomy in the University of London and director of the department of anatomy at St Thomas's from 1899 till 1929. In his early years he had a short experience of private practice, but quickly made the decision to give himself to the scientific side of his profession, with such notable results.

Parsons made many solid contributions to anatomical science and was prominent in the activities of the Anatomical Society. At the time of his death at the age of 80 he was its oldest member, having belonged to it for 54 years. He acted as secretary from 1895 till 1898, was treasurer from 1903 till 1908, and held office as president in 1912–14. He made notable contributions to discussions on subjects on which he had come to be recognized as an authority. In a long series of publications towards the end of the last century he provided a comparative study of the muscular systems of a large number of mammals, in the patterns of which the influences of natural affinity and of functional adaptation were alike recognized. This work was the outcome of meticulous dissection and exact observation combined with careful interpretation, and it remains outstanding principally for the enduring value his records hold for future workers. His masterly Hunterian lectures of 1897 and 1899 summarized the principal results of this phase of his researches. During the same period he published a number of articles on human topographical anatomy, of which particular mention may be made of those dealing with the cervical fascia, the caecum, and the parotid gland. At the same time he was developing his interest in the human skeleton, and published papers on bone and joint morphology.

A new phase in his work came with the examination of individual variation in bones of the human skeleton, which led on to his anthropological studies. Beginning with a survey of the hyoid bone, he produced papers on the English clavicle and femur. He made no attempt at the elaborate statistical methods of treatment subsequently employed by biometricians on similar studies. To their criticisms he pointed out that his data were available for those who cared to analyse them mathematically, and he in his turn criticized the type of mathematician who, with the most elementary biological knowledge, attempts to treat bones as geometrical figures rather than as living structures with a form closely related to function. Parsons's osteological studies led him to the examination of ancient skeletal remains, the comparison of which with modern populations gave him particular interest. He reported on the collections of crania at Hythe and Rothwell in 1908 and 1910 in the *Journal of the Royal Anthropological Institute*. In 1920 he gave an account of the Long Barrow race and discussed its relationship to the modern inhabitants of London, his conclusions being summarized in his book *The Earlier Inhabitants of London* (1927).

During the last war he took the opportunity provided by the presence of German prisoners of war in this country to examine their racial features, and he showed that the "Nordic" contribution to the modern population of Germany is very slight except along the coasts and in the Rhine valley. Subsequently he collected a considerable number of the skulls of Anglo-Saxons who lived in this country, and in 1928 he published an atlas showing the results of his measurements. Many other anthropological contributions appeared at short intervals. Parsons was elected a Fellow of the Royal Anthropological Institute in 1904, was a member of its Council for many years between 1910 and 1930, and held office as vice-president from 1920 to 1923. He was elected president of the Anthropology Section of the British Association in 1927, when he contributed an address on "The Englishman of the Future."

Beside all these activities Parsons concerned himself with the medical curriculum. In co-operation with William Wright he produced in 1912 a short practical dissecting manual designed to focus the attention on essentials and relieve the student of much burdensome attention to detail. This attempt came somewhat too early for complete success, but it paved the way to the present recognition of danger in the over-elaboration of students' textbooks. The London Anatomical Committee, which has played so valuable a part in the maintenance of anatomical supplies to the medical schools of London, virtually owed its creation and preservation to Parsons, who served as its secretary for over fifty years, and many colleagues remember his labours with gratitude.

Parsons was devoted to St. Thomas's, where he spent the whole of his academic career He is remembered by his contemporaries for his zeal in developing the amenities available to students and for his encouragement of a healthy social life in the medical school. A more lasting memorial of the interest he felt for his Alma Mater as well as for his antiquarian leanings is given by his outstanding *History of St Thomas's Hospital*, in three volumes, published from 1932 to 1936. In these he shows us the beginnings of a great London hospital, the development of a medical school at St. Thomas's Street in the Borough, where a part of the St. Thomas's Hospital buildings now remain (with some recent damage) as the entrance courtyard to Guy's Hospital, and the eventual removal of hospital and medical school to its present magnificent and breezy site on the Embankment.

For many years Parsons was an active member of the Society of Apothecaries, in which he attained high office He joined in 1898 and was a member of the Court for the last seven years of his life. He was elected Senior Warden in 1941. For over 40 years he acted as examiner in anatomy to the Society. He also examined for many of the medical schools of Great Britain and Ireland in the course of his long career. His objective outlook and sense of humour are illustrated in the amusement he felt on recalling the irreverent attitude of the students in Dublin to the "foreigner."

Parsons was a man of many activities and wide interests. In later life he recalled that he had sometimes been urged to confine his work to some narrower field. But he maintained his preference for a life in which full rein can be given to one's interests rather than for one in which too much is subordinated to ambition; he had no regrets at having allowed himself a varied life. He was a man of transparent honesty coupled with a bluntness at times disconcerting to his friends. He was an assiduous worker. Even on his holidays he seemed to scorn ordinary delights and lived laborious days. He would make long cycle trips to visit French cathedrals or old English towns. On these journeys he was never happier than when tired out, wet through, and shelterless. On one occasion when an influenza epidemic had come to England he was discovered absent from the hospital. His friends became concerned at this unheard-of thing and sent an emissary to his home to see how ill he was, only to find that he had gone out to "walk it off." A hobby in which he excelled was wood-carving, and his own house was decorated with charming work of his own creation. On his retirement Parsons went to live in lovely surroundings at Princes Risborough, and there pursued his antiquarian bent to the end in the study of local archaeology. During the present war he was compelled to leave this home and went to live at Thame, where he promptly became engaged in an account of local inns, for which this old market town is so well known. And so has ended a fruitful and contented life.

A. B. A.

G. R. FOOTNER, O.B.E., M.B., F.R.C.S.

George Rammell Footner, who died on May 16, was educated at Marlborough, at Pembroke College, Cambridge, and at St. Thomas's. He obtained the University scholarship to the hospital and later on tied with L. E. C. Norbury for the Beaney scholarship in surgery. He was a good cricketer and was one of the outstanding batsmen in his college and hospital teams. He held all the junior surgical house appointments, but when Norbury obtained the surgical registrarship in 1907 Footner went as R.S.O. to the Royal Infirmary, Derby.

In 1910 he joined the Sudan Medical Service, then the most highly qualified though smallest Service of its kind. His work at first gave little scope for his surgical talent, but when the Civil Medical Service gradually took over from the Medical Corps of the Egyptian Army the work in the Southern Sudan, Footner was appointed medical inspector to the Upper Nile Province. With his headquarters at Malakal, and making great use of the Nile hospital ship the *Lady Baker*, which he helped to organize and fit out, he began the pioneer medical work among the Dinka, Shilluk, and Nuer tribes which later on assumed great proportions. Unfortunately an encounter with a wounded lion nearly cost him a limb and resulted in an almost completely ankylosed knee. On recovering from the injury he was transferred to Khartoum as the first senior surgeon appointed in the Sudan Service, which was then passing through a stage of rapid development. Later he became as well the first lecturer and teacher of surgery in the newly constituted Kitchener Medical School. In 1928 he retired from the Sudan and from medical practice, living first at Winchester and later in Cornwall. At the outbreak of war he undertook work of various kinds, mainly medical boards and helping in local general practice.

Footner's tall spare athletic figure commanded attention. He was a fine example of the type of surgeon most needed in the Tropics, where character and example as well as professional ability are particularly important. He had strong sensitive hands and a sound surgical technique. A man of high purpose, he demanded a very efficient standard from others as well as from himself. He was intolerant of anything slipshod or second-rate, and he exercised an enduring influence on those Sudanese medical students that were the first to pass through the Kitchener School. He bore his last illness with exemplary courage and fortitude and was actually working to within ten days of his death. He leaves a widow, a daughter and two sons, and a large circle of friends and acquaintances to mourn his loss.

H. C. S.

G. F. WILSON, L.M.S.S.A.

We regret to announce that Dr. G. Frederick Wilson, secretary of the West Ham Panel Committee and a former chairman of the Stratford Division of the B.M.A., died on May 20. The following tribute comes from H. C. B.:

The foundations on which any edifice is built are rarely, if ever, exposed to view. Yet without them the visible superstructure could not be erected, or, if erected, would be in imminent danger of collapse. This generalization is as true of associations of human beings as of conglomerations of building materials. The bedrock on which our Association is founded is not its house, its officers, its Council, its A R.M., or any such visible manifestations—it is the work done by a number of hard-working loyal disinterested colleagues who undertake the routine day-to-day work of professional organizations. Much of this work is unseen and unsung, except by those in intimate contact with it—yet without it our Association would be moribund instead of full of vitality. A fine example of such a colleague was Dr. G. F. Wilson, whose death will be felt widely in professional circles. Son of a West Ham doctor, he received his medical education at the London Hospital and then followed his father in his practice. Here the greatest part of his professional life was spent, and here he showed those qualities of painstaking detailed work for his colleagues which bound him so closely to those associated with him. He was chairman of the Stratford Division for two periods, a member of its executive committee for many years, and one of its representatives to the A.R.M. on eight occasions. He was secretary of the West Ham Panel Committee and chairman of the Insurance Committee twice, occupying this position at his death; he was also chairman of several of its subcommittees. Dr. Wilson took a considerable part in the building of the Essex Public Medical Service, of which he was a past chairman. He was also active in medical golfing circles and was secretary to the Stratford Medical Golfing Society. Dr. Wilson retired from practice before the outbreak of the war, but later took up the position of medical officer of civil defence for the western area of Essex. Here also he built up for himself a reputation for hard work and loyal service and became popular amongst his colleagues. In wishing him farewell, and extending their sympathy to his widow, herself a good friend of ours, members of the Stratford Division realize what a difficult place to fill will be that occupied by Dr. Wilson.

LESLIE J. PATON, F.R.C.S.

We regret to announce that Mr. Leslie Paton, consulting ophthalmic surgeon to St. Mary's Hospital and the National Hospital, Queen Square, died in London on May 15 after a long illness.

Leslie Johnston Paton was born in Edinburgh in 1872 the second son of James Paton, F.L.S., Curator of Picture Galleries and Museums. The family migrated to Glasgow when he was 4 years old, and he later attended Glasgow High School and the University, passing on to Caius College, Cambridge, with a scholarship in 1891. There he remained for six years, teaching botany and physiology until he entered St. Mary's Hospital in 1897. At the same time he joined the teaching staff of his friend T. M. Taylor (afterwards Sir Thomas Taylor), who was head of Wren's coaching establishment, in Powis Square, Bayswater, teaching physiology to help his then slender finances. Qualifying B.Ch.Cantab. in 1900 he became house-surgeon to Edmund Owen at St. Mary's in 1901, and took the M.B. and F.R.C.S. a year later. He demonstrated anatomy during that year, and was then appointed assistant ophthalmic surgeon to Henry Juler, succeeding to the senior post in 1911. Meanwhile, in 1907, he had been appointed to succeed Marcus Gunn as ophthalmologist to the National Hospital, where for the four remaining years of Hughlings Jackson's life Paton followed the teachings of that great neurologist. Twenty years later he inaugurated the endowment of the Hughlings Jackson lecture during his term of office as president of the Neurological Section of the Royal Society of Medicine. Paton had the double distinction of being chosen president both of that Section and of the Ophthalmological Society of the United Kingdom. At the Annual Meeting of the British Medical Association in 1909 he was secretary of the Section of Ophthalmology and in 1934 he served as president. He had been treasurer of the International Ophthalmological Council and was an honorary member of numerous foreign ophthalmological societies. He contributed many notable papers to the literature of his subject, the most important probably being "The Pathology of Papilloedema" in *Brain*, 1911, and "The Classification of Optic Atrophies," 1930. His Mackenzie Memorial Lecture in 1937 was devoted to optic neuritis. As chairman and managing director of the *British Journal of Ophthalmology* he wielded much influence and was ever on the look-out for rising talent.

Dr. WILFRED HARRIS writes:

Paton's only form of exercise of late years was golf, of which he was very fond, though never pre-eminent at the game. For years he used to spend his summer holiday on the Elie links in Fifeshire, and later he built a country house on the Wentworth Estate, Virginia Water, near the tenth green of the main course, which he named appropriately "Scotch Corner" Here, on the annual competition days for the "Paton Cup," which he had presented to St. Mary's Hospital Medical School, he and Herbert Smale would meet the tiring competitors and reinvigorate their strained nervous systems with mugs of beer. These annual holidays were much looked forward to by students and staff alike, whom Paton insisted on being his guests for the day.

Leslie Paton made few, if any, enemies, though he was highly successful in practice. His brain was brilliant and analytical, but he took his time in making up his mind. Though unknown personally to the present generation of students at St. Mary's he will be long remembered by his friends and generations of past students for his teaching, his balanced mind, and his cheery disposition.

Dr. DANIEL MILLAR, who died at his home in Rutherglen after a short illness, was a magistrate of Glasgow and for the past five years had been representative of the Dalmarnock Ward in the City Corporation. In his youth he had worked as an engineer in a Clyde shipyard and studied to become a medical student in his spare time. Dr. Miller took the Scottish triple qualification in 1930. In 1941 he was awarded the M.B.E. for the heroic part he played in the rescue of an injured man during the heavy air raids on Clydeside. With Dr. McLaren Ord he crawled through a tunnel made among the ruins of a bombed tenement, and under the light of torches amputated one of the man's feet while the debris threatened to collapse at any moment.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

On June 1 Dr. T. Shirley Hele, Master of Emmanuel College and representative of the University on the General Medical Council, was elected Vice-Chancellor for the ensuing academical year.

Ronald Aylmer Fisher, Sc.D., F R.S., of Gonville and Caius College, has been elected to the Balfour Professorship of Genetics from Oct. 1, 1943.

Joseph Stanley Mitchell, M.B., B.Chir., Ph D., formerly Fellow of St John's College under Title A, has been elected to a Fellowship under Title E.

At a Congregation held on May 22 the following medical degrees were conferred:

B CHIR.—A. W. Capon, G. F. Panton (by proxy), F. M. P. Eckstein (in person).

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—J. D. Abbott, J. V. Aveling, A B Backus, T. E. Barwell, Annette G Bauer, Margaret E Berry, Isobel P Beswick, Margaret A. Billinghurst, J. Birch, W B N Bomford, G. L. W. Bonney, C. Boroda, P W. Brand, A. R Brandreth, D B. Brewer, F. B Bromfield, R J. Bush, N R. Butler, L. Capper, G. M. Coupland, W. G Cross, J. B M. Davies, R G. Davies, D Dewhirst, F G B. Dodd, J T Doyle, A. Elton, D A. T. Farrar, T. R. Fink, H J. W. Fisher, R. J K. Fleming, A W. Fowler, W. Fox, Edith V. Foyle, R. S. Francis, T L Frank, J. H. Friend, P. S. Fuller, D. S. Gibbs, G. H. Gilford, T. H. B Gladstone, K Greenwood, G. Gremson, R. F. Griffith-Evans, T. A Grimson, D L. Gullick, H. C Hamilton, W J. Hanbury, B. H. Hand, S. F Hans, J Hardwicke, D M. Hare, E J. Harries, H J Harris, M F. Hart, L. W Hefferman, Margaret I. Hendrie, K R. Hill, E. O. Hohn, M. Holborow, F. C. N. Holden, Reba N G. Holloway, Betty D Holt, J. P. Hopewell, J F. Horley, D. D. C. Howat, J. G. Howells, N. H. Howes, W H Humphreys, A D M. Jackson, G A. James, Elizabeth M. Jenman, E. L John, J. L. Jones, R N. H N. Kahan, Mary P. Karney, Madeline K. Keech, P R N Kerr, M. Knowles, S. Kramer, P L. Langton-Lockton, D. Lawrence, J. Lee, A. M. Levy, J. Lister, R I. McCallum, I. S. MacLeod, Madeline J. MacKenzie, A. C. Macrae-Gibson, L. J. Morgan, N. F. Morris, P B. Newcomb, Edith F Newling, Helen M. Noble, C. C Packman, F T. Page, B. D Patel, A. C. Pearson, R J. N. Pellow, A B. Philip, M P. Pick, Dorothy P Potter, Mary Pringle, G. S. Ramsay, A. J. M. Reese, S M A Rizvi, M Roth, J. W. P. Salt, Isabel B. Schooling, J. Sebel, R E Shaw, R. G Sheppard, A. J. Shillitoe, Esther E. Simpson, P. J. Spencer-Phillips, D. A Stanley, A. Stoddard, B. Stone, D G H. Stone, A. B Stratton, D. F Street, R J. C. Sutton, J. McN. Tainsh, G W. Taylor, M. V. P Thomas, B E Tomlinson, P. A Trafford, Frances M Ulyatt, E Waddington, G. Watkinson, C E. C Wells, H Whitworth, E. A Williams, J. R. F. Williams, Marion Williams, Mary F. Wright, J. A. H. Wylie, Judith C M. Yuill, J. H. S Zibll.

UNIVERSITY OF EDINBURGH

The Medical Faculty of the University of Poland was established within the University of Edinburgh in order to keep together a group of Polish professors, physicians, and other medical workers, to give them an opportunity for research and teaching, and generally to keep an eye on the academic spirit, so that at the end of the war Poland would have at least one active medical school. The project has already met with much success, and there is now a Polish hospital associated with it for clinical work. The course of study and the examinations are arranged to fulfil the requirements of the Polish law and so far as possible to approximate to the Edinburgh standards. At a recent ceremony in the M'Ewan Hall, attended by representatives of the University of Edinburgh and the Polish Faculty of Medicine, the President of the Republic of Poland conferred the Order of Polonia Restituta on Sir Thomas Holland, D.Sc., Vice-Chancellor and Principal of the University of Edinburgh; Prof. Sydney A. Smith, M.D., Dean of the Faculty of Medicine; and Prof. F. A. E. Crew, M.D., in recognition of the "great service which the University of Edinburgh has rendered to Poland by the invitation to found a medical school within her walls." His Excellency, in the course of his address, said that it was a historical moment when, in March, 1941, Edinburgh solemnly inaugurated the Polish School of Medicine in a memorable ceremony in that hall. He was therefore happy to express in the same place his gratitude, and the lasting gratitude of his country, to three of the eminent scientists of Edinburgh University, who were responsible in the first instance for this magnificent testimony of brotherhood and common idealism.

The Services

The D.S.C. has been awarded to Surg. Cmdr. J. L. S. Coulter, R.N., and Temp. Surg. Lieut. J. G. C. Murray, R.N.V.R.

Temp. Surg. Lieut. R. S. Slessor, R.N.V.R., has been mentioned in dispatches.

Capt. A. R. P. Ellis, R.A.M.C., has been awarded the D.S.O., and Capts. J. H. Dorman and W. G. Edwards, R.A.M.C., have been awarded the M.C., in recognition of gallant and distinguished services in the Middle East.

The following medical officers have been mentioned in dispatches: Air Vice-Marshal A. E. Panter, K.H.S.; Acting Group Capt. C. J. S. O'Malley; Wing Cmdrs J. P. Huins, O.B.E., A.A.F., T. C. Macdonald, A.F.C., R. Thorpe, J. H. Williams, A.A.F., O. S. M. Williams; Acting Wing Cmdrs. R. W. Durand, R.A.F.V.R., J. S. Wilson; Squad. Ldrs. H. S. Barber, D. G. Evans, R.A.F.V.R., K. B. Redmond, (Mrs.) A. L. J. Dovey, D. Stafford-Clark, R.A.F.V.R.; Fl. Lieuts. J. L. Morgan, R.A.F.V.R., T. Hepburn, R.A.F.V.R.

CASUALTIES IN THE MEDICAL SERVICES

Capt. **SAMUEL DAVID CORRY**, who has died of wounds as a prisoner of war, studied medicine at Belfast, graduating M.B., B.Ch., B.A.O. of Queen's University in 1938. He joined the R.A.M C. at the end of 1939 and was promoted twelve months later. He was mentioned for gallant and distinguished services in the *London Gazette* of April 3, 1942, and was reported missing after the Dieppe raid.

Flying Officer **ARCHIBALD CLARK WARNOCK** was killed in a flying accident on May 7. He was born in Dec., 1917, studied medicine at Glasgow University, and qualified M B., Ch.B. in Oct, 1940. After holding house appointments at the Royal Infirmary, Glasgow, and at Motherwell, he was appointed to a commission in the Medical Branch of the R.A F.V.R. in May, 1942. At the time of his death he was medical officer to a Fighter Squadron.

Died of Wounds.—War Subs. Capt. W. D. Miles, R.A.M.C.

Prisoner of War.—Major W M. Stewart, R.A.M.C.

Wounded or Injured.—Temp. Surg Lieut. R. B. Stark, R.N.V.R.

Medical Notes in Parliament

REORGANIZATION OF MEDICAL SERVICES

In the House of Lords on June 1 Lord **DERWENT** initiated a debate on the Beveridge report and the medical services. He moved that as the medical provisions of the Beveridge plan concerning the future status of doctors and the medical treatment of the population in general did not appear to be designed to further the best interests of British medicine or of the population, the Government should not adopt them without careful examination. He quoted the address by Dr. Hill, Deputy Secretary of the B.M.A., at a meeting of the Metropolitan Counties Branch of the Association on the tentative proposals of the Government for implementing Assumption B of the Beveridge report.

Lord **DAWSON** pointed out that the organization of a comprehensive medical service was no new subject to the medical profession. It had been under consideration since 1920, but the demand for it had always been received by Governments with deaf ears. It was not till the Beveridge report came out that any idea of a comprehensive medical service was put on the political map. The Government had introduced a state of haste and hustle into what, in the words of the Prime Minister, should be a gradual process spread over four years, and they expected the whole medical profession to be turned upside down in six weeks. All he could say was that it was not going to happen so long as they were there to prevent it. It was the duty of the medical profession to devise the best service on its merits which would bring about that improvement in the health of the nation which all were agreed in desiring. It would be disastrous if doctors were regarded as agents to control benefit in the interests of the social security fund.

The first and most important thing to do was to bring together preventive and curative medicine into a single service, so that the furtherance of health, and especially the personal health service, would be brought within the ambit of medical practice, both individual and institutional. Preventive and curative medicine should be brought into the structure of every teaching hospital and occupy an important part of medical education. The second foundation was a pattern of health and inter-related hospital services, distributed according to the needs of the population, in areas sufficiently large to secure a good and efficient service, with, at the head of each area, a key hospital which would afford intellectual leadership to the whole area. That would be done by close co-operation between the local authority and the voluntary hospitals working together in partnership.

Local Administration

Lord Dawson admitted local government in some form to be the seat of the ultimate administrative authority. That would not only conform to constitutional usage, but to the fact that local government already administered health services and its own hospitals. On the other hand, the voluntary hospitals, which had the bulk of the experience, demanded their partnership, and the medical profession would refuse to accept such local administration unless the latter were guided by representative expert bodies. It was not to be expected that a learned profession was going to give up its freedom to think and do as it considered best. The only way of solving the difficulty of the local authority being accepted as the ultimate administrative agent was by having at the elbow of each health authority in each area an advisory council consisting of representatives of the staffs of local government and voluntary hospitals, a considerable proportion of whom would be medical men.

As a profession they would support the proposal that health services and hospitals must be referred to a larger health authority corresponding to each area. This would involve a combination, in many instances, of major local authorities for that purpose. Provided that authority followed the precedent of the education authority and permitted the co-option of a minority of non-elected members—people chosen from among those who had special knowledge and experience of the subject—he believed that along those lines a practical scheme lay. If, in addition, side by side with each area authority, there was an advisory body such as that to which he had referred, and if the principles of health and hospital authority were laid down by Whitehall, he believed that in some such alliance was to be found a solution of their difficulties in regard to hospital services. Not the least of the merits of these area advisory bodies would be that they would bring together the leaders of all kinds of hospital and health services whether they belonged to the local government administration or to voluntary hospitals. It would take two years of patient work to bring about agreement on the many conflicting interests.

Meanwhile hospital and consultant services would be remunerated by appropriate salaries, and holders of these posts would serve on a part-time or a whole-time service, according to choice and circumstances. During the foundational two years they would see where lay the advantages and the disadvantages of a part-time or whole-time service. In regard to hospitals, though every patient would have the same essential treatment, it would be wrong for them all to have the same dead level of amenities and accommodation. The Beveridge plan only provided essentials for the hospital service. One of the things they were most proud of in their hospitals was that every patient in essentials received the same standard of treatment, and, while they secured equality, for Heaven's sake let them avoid a deadly uniformity.

Turning to health centres, Lord Dawson said that Government after Government had treated the matter with complete indifference, and now at the last moment the Minister of Health woke up and talked about health centres dotted about the country when they had never put the health centres to the test of experience. Although he believed they opened a big field of usefulness for the public, he would be a foolish man who would put health centres into service till he had tested them out and proved whether they were good or bad, and had improved them in the light of experience. Therefore when he saw health centres being used as an excuse for the bringing in of a whole-time salaried service he became suspicious.

Hustle of Political Exigency

The medical services sponsored by the different Government Departments must come in under the same umbrella and be governed by the same broad principles of policy under the Ministry of Health. They could have no contracting out. He referred, for instance, to mental health, to the school medical services, and to industrial medicine of the Ministry of Labour. The Ministry of Health had given way to the hustle of political exigency and was trying to put up a structure in a few weeks which it was beyond the wit of man to do. It would be nothing but a jerry-built structure if anybody tried to build it in its completion now. If that were attempted it would arouse a degree of antagonism and distrust which would bring any scheme to the ground. He referred in particular to their discovery of the idea of a whole-time salaried State service for all doctors as being in the departmental mind. Without the foundations of the service even being laid, to endeavour to enclose all doctors within a bureaucratic ring fence was sheer madness. It might be right ten years hence, but it was sheer madness now. The very mention of it had already produced a degree of distrust and antagonism which, unless something was done to allay it, would bring permanent harm to the prospects of peace. Doctors would not take employment with a local authority naked and unadorned, at any rate not now. There was too much distrust. The medical profession would not consent to be pawns on the local government chessboard. They would not consent to have a highly skilled profession governed by laymen ignorant of medicine who had been elected on a totally different ticket.

In the endeavour to be constructive a great deal of time had been given to reconciling these two difficulties, and it could be done by each local authority setting up a special local health authority with a co-opted minority to act as an advisory council. Its members should include doctors in private practice and hospital experts, including representatives of local government hospitals, because the doctors in those hospitals suffered from having too little power. They had no medical council, and were under the medical superintendent and all the tyranny that that represented. They wanted a change. Let them all meet as an advisory council. It should be made statutory that local authorities must give serious attention to their advice, and then he would be content to leave the decision to the local authority. But all that machinery would come to the ground if anybody suggested such a ridiculous scheme as whole-time State salaried service for the whole medical profession. He admitted that with the passage of time many of them might alter their ideas with regard to the relative merits of whole-time and part-time service. He believed that in the course of the next few years professional earnings would consist of a larger proportion of salary than hitherto and a smaller proportion of fees. That did not frighten him, provided it was done freely in the light of experience.

A Medical Council

Lord MORAN, in a maiden speech, said all activities concerned with health should come under one department and not under six departments, as at present. It was essential that in the Ministry of Health civil servants who were not doctors, and doctors who had long been divorced from the work of medicine by administrative duties, should keep in close touch with those actively engaged in the practice of their profession. How could that be done? He thought advisory committees had become rather discredited in the profession. They appeared to have little power, and the Minister was apt to lose interest in their activities so that sometimes they did not meet for six months or even a year. He had in mind a medical council which should help to frame the policy of the Minister. It should meet regularly and not deal with a fragment of policy every six months. It should deal with all questions of general policy that came up. It should be free to publish from time to time uncensored reports of its activities. Such a council might be composed, say, of twenty medical members—fifteen perhaps elected by the profession and five appointed by the Minister, including the Ministry's Chief Medical Officer. The council would elect its own chairman. He hoped that the Minister would give this council real power. The real opposition to the proposals for a comprehensive medical service was based on the objection of the medical profession to become employees of local authorities. If that was to be overcome it was clear that there would have to be some machinery for referring disputes between the authority—whoever that might be—and the doctors working for that authority to some central court of appeal, and this council might very well act as that court of appeal. Further, a sub-committee of the council could act as an appointments bureau, finding posts for doctors in the parts of the country in which they desired to settle and providing for the authority lists of suitable applicants. It could also administer a superannuation scheme for every doctor in the service, if the service did eventually come.

The second essential was clearly that the conditions under which the rank and file of the profession worked must be made as perfect as they could be made. If doctors, instead of practising at their own houses, were to be banded eight or nine together, and were to see patients at some house built for the purpose, with facilities for diagnosis and with consultants' services at their elbow, they would breathe again that atmosphere of their student days in the wards, and it would be a great gain to the community. The fact must be faced that the majority of doctors at the present time were opposed to these health centres. Certainly members of the public were highly suspicious of them, and on very good grounds. None of these centres had been built. There would be plenty of time to try them out. The question of the local authority was really a thorn in the flesh of the profession. Perhaps the country could be divided into ten or twelve regional administrative units, each working with a university, and from which all local feeling and influence would be excluded. It would be useless to try to dragoon doctors to work under local authorities unless some measure of reassurance could be given them that what was to be done would not interfere with the proper work of their profession.

Consultant Service

The third essential was that there should be a really good consultant service. There was general agreement that everyone, whatever his means, must be able to get consultant opinion when necessary. There were not enough consultants at the present time, and those available were not distributed according to the needs of the community. To get over the difficulty in this connexion they must know how many consultants there were and where they were.... They must have a list. No such list existed at the present time. Three Royal Colleges had agreed to draw up such a list for the Ministry of Health. In the first instance, this list or register must be drawn up on one criterion only: the approval of the profession in the man's neighbourhood that he was a proper consultant. It followed, therefore, that all these lists must be drawn up locally; and in the twelve university cities in England, Wales, and Northern Ireland committees were now sitting. The Vice-Chancellors of all those universities had consented to act as chairmen of those committees. When this list was complete a very different state of affairs would follow; any man who aspired to be a consultant after that, and to have his name added to this list, would have to pass the very strictest scrutiny. He would have to satisfy a board that he had done the years of special training required, and that he was competent to act as a consultant. When all this was done, and when everyone was able to obtain the services of a consultant who had had a proper training, it would be the greatest single step in advance in his own lifetime.

Lord GEDDES said that the only thing that could be done at present to get the medical profession out of the state of alarm which existed was for the Government to make it quite clear that they did not intend to turn every registered medical practitioner into a whole-time servant of the State—because that was what was feared, and not by members of the medical profession alone. There was now developing in this country a rather violent reaction against bureaucratic interference in private life. It was the fear of that bureaucratic interference in private life which was making a very large number of people anxious about the Government's proposals, and about negotiations now proceeding between the Government and the medical profession.

Government Reply

Lord SNELL said he had not really gripped what particular sin the Government had been guilty of in this matter. The principle enunciated in the motion—namely, that any proposal for comprehensive health service should be carefully examined and that no hasty decision should be taken—was precisely the policy of the Government. It was enunciated with perfect clearness by Sir John Anderson in the House of Commons on Feb. 16. The motion implied that the Beveridge report contained detailed proposals about the future status of doctors and the medical treatment of the population, but the Beveridge report itself expressly declared that the problem of the organization of a complete health service was outside the scope of the report. Lord Moran had spoken about the reluctance of medical men to become servants of local authorities. With some knowledge of English local government he (Lord Snell) stated quite firmly that that was not his experience. It was not the experience of any member of a selection committee of a local authority. Lord Geddes had suggested that the whole idea of a salaried service should be abandoned. The Government had made no final decisions about this matter. To the suggestion that a Royal Commission should be appointed without delay the answer was that discussions were proceeding with the medical profession, and if it should turn out that a Royal Commission would be the best instrument the Government would look at it in that sense. The medical profession was being consulted at every stage. The Government had initiated discussions with groups representative of the medical profession, the voluntary hospitals, and the major local authorities, and it was expected that before long the Minister would be able to review the question of organization and to formulate further proposals for public discussion. It was not intended that the decisions so far made should be final or binding.

The Government were not trying to rush this question. They were allowing full opportunities for calm and full discussion.

Industrial Accidents.—Accidents reported under the Factories Act were: 1939, 1,104 fatal and 192,371 non-fatal; 1940, 1,372 fatal and 230,607 non-fatal; 1941, 1,646 fatal and 269,652 non-fatal; and for 1942, 1,363 fatal and 313,267 non-fatal. The percentage of such accidents to the total employed was roughly 3.4 in 1940 and 3.8 in 1941.

No. 20

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 22.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for. (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1943					1942 (Corresponding Week)

† Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

Medical News

A meeting of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health will be held at Tavistock House, Tavistock Square, London, W.C.1, at 3 p.m. on Friday, June 18. The subject for discussion will be "Diphtheria—Some Problems of Administrative and Clinical Control." Opening speakers: Dr. J. A. Scott (M.O.H., Fulham Met. B.), Dr. N. D. Begg (Med. Supt., Eastern (L.C.C.) Hospital), and Dr. R. Cruickshank (Group Pathologist, L.C.C.). A cordial invitation to attend is extended to members of the Metropolitan Branch of the Society.

The House of the British Medical Association will be closed from Friday, June 11, 6 p.m., to Tuesday, June 15, 9 a.m.

On Thursday, June 17, at 4 p.m., Mr. F. J. Chittenden will give a Chadwick Public Lecture on "Plants causing Irritation," at the Chelsea Physic Garden, Swan Walk, S.W.3. Admission is free without ticket.

At a meeting of the British Association of Physical Medicine, held on May 25 at the Medical Society of London rooms, Lord Horder presiding, the election of the Council was completed. The following are its members, who will hold office until the annual meeting: Drs. F. Bach, L. D. Bailey, P. Bauwens, W. Beaumont, Wing-Cmdr. Bromley, Drs. Hugh Burt, F. S. Cooksey, E. J. Crisp, C. B. Heald, Geoffrey Holmes, Lord Horder, Brig.-Gen F. D. Howitt, Dr. James Mennell, Major J. W. T. Patterson, Dr. M. B. Ray, Sir Morton Smart, Dr. Kenneth Stone, Major Tegner, Dr. Dorothy Wood, Sir Robert Stanton Woods. The Council was authorized to draft a declaration of the objects of the Association; the rules as to membership, procedure, etc., to be guided in these matters by resolutions passed at the previous meeting on May 5. It was also empowered to appoint the officers of the Association.

The attention of doctors generally, but especially of those in London, is drawn to yet another activity of the Joint War Organization of the British Red Cross and the Order of St. John. At 25, Cadogan Square the organization has established a sick-bay for the care of civil defence workers of both sexes and of Red Cross and St. John personnel who are not ill enough to go to hospital but need a brief period of nursing in bed. There are 26 beds for patients suffering from such conditions as influenza, acute bronchitis, jaundice, minor accidents, and overstrain, and patients needing a few days in bed after discharge from hospital are also admitted. Two doctors are attached to the sick-bay and a trained nurse is in charge, but patients can be admitted under the care of their own doctors if they wish. No charge is made, but of course a donation to the funds of the organization is most acceptable.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* whooping-cough notifications rose by 340, measles by 345, and dysentery by 48, but there was a decline of 40 in acute pneumonia.

Five Northern counties recorded rises in whooping-cough: Lancashire 87, Yorks West Riding 61, Warwickshire 53, Cheshire 48, Derbyshire 44.

The higher incidence of measles contrasts with the trend during the preceding seven weeks, when the cases fell by 11,529. Especially notable were the rises in Staffordshire 182, Northamptonshire 91, Northumberland 74, Kent 72, and Shropshire 55. Fewer cases were notified in a number of counties, and the largest declines during the week were in London 88, and in Norfolk 76.

The higher figure for dysentery was due mainly to sporadic cases. In Gloucestershire cases rose from 9 to 19 (all in Bristol C.B.), in Lancashire from 23 to 37, and in Yorks West Riding from 2 to 12. Six county boroughs in Lancashire accounted for 29 of the county total (Manchester C.B. 12). The 12 cases in Yorks West Riding occurred in six administrative areas.

In *Scotland* notifications of dysentery rose from 41 to 73: city of Aberdeen 24 cases, and Banff county 23. In the eastern area 32 cases of diphtheria were recorded, compared with 14 in the preceding week. There were 19 more cases of whooping-cough, but the notifications in Glasgow fell by 31.

In *Eire* the notifications of diphtheria were the lowest of recent months, but those of typhoid were the largest—the 15 cases being reported from eight administrative areas (Kerry, Tralee R.D. 6).

The Week Ending May 29

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,997, whooping-cough 2,233, diphtheria 712, measles 7,395, acute pneumonia 760, cerebrospinal fever 80, dysentery 116, paratyphoid 10, typhoid 5.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary.

TELEPHONE No.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London;* SECRETARY, *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Oral Blood-blisters

Q.—*A lady aged 72 suffers from recurring blisters on the lips, hard palate, and pharynx at irregular intervals. The blisters appear quite suddenly, usually singly, and are filled with blood-stained fluid. She is of an emotional type but is in fairly good health. What treatment is recommended?*

A.—The recurrence of solitary blood-stained vesicles on the lips in an emotional subject is most suggestive of an unconscious autophytic phenomenon, and a sedative bromide mixture would probably be the best method of treatment. On the other hand, the patient may be allergic to some food or tooth-paste, and this would explain the oedema, which, presumably, accounts for the hard palate and pharynx. The solitary blood-stained lesion is against the diagnosis of allergy, but, presuming the condition is an allergic one, calcium and vitamins A and C might be tried.

Addiction to Nutmeg

Q.—*I have just come across a very strange form of addiction in a man whose general health and appearance are bad. He continually chews nutmegs. I should be glad to have any information about the harm that might accrue through this habit.*

A.—On page 168 of the 1942 edition of Sollmann's *Manual of Pharmacology* the following paragraph appears under the heading of "Nutmeg Poisoning": "In man severe symptoms have occurred from one to one and a half nutmegs, or from a teaspoonful of powdered mace. The effects appear in one to six hours, and are mainly narcotic, varied by excitement and delirium, with some motor stimulation and local irritation; they usually end in recovery in twenty-four hours. Nutmeg is also ecbolic. Similar effects occur in animals. Hepatic necrosis has been demonstrated in cats (Dale, 1909). Cushny and Wallace, 1908, showed that the narcotic effect is produced by 'myristicin,' the high boiling portion of the volatile oil. The oil has been investigated chemically by Power and Salway, 1908. *Myristica,* U.S.P. (nutmeg) is the ripe seeds of *Myristica fragrans.* Dose, 0.3 to 0.6 g., 5 to 10 grains. The *Oil,* U.S.P., is distilled from the seeds. Dose, 0.06 to 0.2 c.cm., 1 to 3 minims, *B.P.* The *Spirit* represents 10% of the oil. Dose, 0.3 to 1.2 c.cm., 5 to 20 minutes [*sic:* presumably minims]."

The Colour of a Bruise

Q.—*A bruise passes through various hues to reach a jaundice-yellow colour. Shed blood and blood massively segregated in the body in cysts and blood-blisters do not undergo these pigmentary changes. What causes the changes, what cells are concerned, and is the process similar to bile formation by the liver?*

A.—No pigmentary changes occur in shed blood unless as the result of decomposition. The haemoglobin from blood in an enclosed body cavity or space is acted upon only by tissue enzymes, and the new pigment formed is haematoidin, which gives such material its chocolate-brown colour. Red cells effused into connective tissue are attacked by histiocytes, which form bilirubin from them, the yellow colour of such an area being due to the presence of this pigment. Whether bile pigment is formed from extravascular blood therefore depends on whether it is accessible to the phagocytic cells of the reticulo-endothelial system. Bilirubin so formed in any part of the body (a process which is normally continuous owing to the removal of effete red cells from the circulation) is excreted by the liver in the bile.

Pathology of Atypical Pneumonia

Q.—*Is the condition known as primary atypical pneumonia an interstitial pneumonia?*

A.—As far as is known—yes. When it has been possible to examine histologically the lungs from cases of this condition, the primary changes appear to have started in the alveolar walls. The exudate which later appears in the alveoli consists of serum, mononuclear cells, desquamated epithelial cells, red blood corpuscles, and polymorphonuclear leucocytes, and the consolidation, when it occurs, is not as dense as in a lobar pneumonia. The view that the condition is primarily an interstitial pneumonia is supported by the x-ray findings, which show as a rule either a reticular shadow or, if a whole lobe is involved, a lobar shadow of only moderate density.

Oral Administration of Liver Extracts

Q.—*As liver therapy was originally oral—raw liver, partly cooked liver, various liver extracts, etc.—is there any reason why the perfected liver extracts could not be administered orally?*

A.—It is generally agreed that the injection of liver extract is 20 to 40 times as effective as oral administration. To treat a patient with anahaemin by mouth it would therefore be necessary to give 200 mg. a day instead of once a month by injection. In other words, the cost of treatment would rise from 4s. 6d. a month to 4s. 6d. a day. It is for this reason that the Government has discouraged the oral administration of liver extracts during the war.

Treatment of Myasthenia Gravis

Q.—*A patient aged 23 years developed myasthenia gravis five months ago. Treatment with prostigmine, ephedrine, glycine, and potassium salts is being given, but loss of weight and muscular power continues. Deep x-ray therapy to the thymus gland is now contemplated. What percentage of success has been obtained with this treatment? What other lines of treatment are available?*

A.—One of the peculiarities of myasthenia gravis is the way in which different cases respond differently to different methods of treatment. There is little real evidence that glycine is of any value, but ephedrine and potassium are both useful, particularly in the less severe cases. Prostigmine has proved of great benefit, but some authorities have preferred to limit its use to the times when the myasthenic is greatly disabled by muscular weakness, and particularly when the weakness is embarrassing respiration, as it does in the actue exacerbations which are called myasthenic crises. The reason for this choice is that prostigmine increases the power at the time, but a few hours after the injection has been given the muscles may be even weaker than they were before. This effect has been likened to flogging a tired horse, and the cause may be that if, as was outlined in a leader in this *Journal* on May 1 (p. 544), an abnormal substance is circulating in the blood which destroys one of the precursors of acetylcholine, the prostigmine is merely facilitating the action of the acetylcholine which is not destroyed, and the real pathological process is going on undisturbed or may even be enhanced by the extra acetylcholine which has been made available by the prostigmine. This is, of course, pure speculation.

Deep x-ray treatment to the thymus has been tried on several occasions, notably at the National Hospital, Queen Square, but workers there have now discarded the method as of little value, and the procedure is not even mentioned in Davidoff and Dyke's new book *The Roentgen Treatment of the Nervous System*. A case such as the one described fulfils many of the requirements which are found desirable in advising thymectomy. Keynes, who recently reported his operative results to the Royal Society of Medicine, has found the effect to be most dramatic in the severe and acute myasthenic who shows generalized weakness. Failure to respond to medical treatment is of course another indication for operation. It is likely that even in this case prostigmine will be beneficial if given in sufficiently large doses, and Keynes has found that really enormous doses are needed to combat the acute myasthenic crisis that occurs after operation. It has been said earlier that some neurologists prefer to reserve the use of prostigmine for these crises, and if operation is considered it would be well to withhold this substance until the patient is handed over to the surgeons. Provided the patient survives the immediate post-operative stage, which is usually critical, the results of operation in this type of case have been dramatic.

INCOME TAX

Appointment—Receipts " in Kind "

" P. Q." is a married woman employed as an assistant at a salary plus " full residential emoluments " for herself and her husband. Is her or the husband's keep liable to tax?

⁂ The value of neither her own nor her husband's keep is assessable; but the result would be different if the terms of the engagement provided for a gross amount of remuneration, subject to deduction for the " keep " provided, as in that case the gross amount is liable to assessment. (The fact that the cost of the " keep " is not assessable on the recipients does not affect the principal's right to treat it as a professional expense.)

Wife's Part-time Earnings

E. W.'s wife has done 12 weeks part-time work as dispenser to the partnership and has been paid £30. He asks, " Do I pay full rate of tax on this? "

⁂ There is a special personal allowance (in addition to the ordinary " married " allowance of £140) up to a maximum of £80 in respect of a wife's earnings. Mrs. E. W.'s earnings of £30 are covered by this £80 and there is accordingly no liability to tax thereon.

War Damage Contributions

J. A. B.'s claim to deduct as professional expenses the contributions paid under the " business scheme " and in respect of the professional portion of the premises has been refused. Is this correct?

⁂ Yes; such deductions are expressly forbidden by Section 84 of the War Damage Act of 1941. (The reason for this is presumably that the Government have undertaken to contribute to the Fund from the Exchequer, and to permit deduction for income-tax purposes would in effect amount to a further contribution from the Government revenues.)

Necessitous Practices Fund

" X Y." Owing to a long period of illness this correspondent received a sum of money from the special fund for " necessitous practices " of the National Health Insurance Committee, for one year. Is this liable to tax?

⁂ The grant is liable to tax if it can be claimed as of right, or if, though not so claimable, it has been made substantially in respect of the services rendered by the practice. " X. Y." might like to put the facts before the Board of Inland Revenue (address: Imperial Hotel, Llandudno) for their ruling; we would not advise contesting the decision if it should be adverse.

LETTERS, NOTES, ETC.

Wheeled Stretcher Carrier

Col. J. GRAHAM MARTIN, A.M.S., T.A. (ret.), writes from Liverpool: Neither Lieut.-Col. C. A. Whitfield (May 22, p. 648) nor Dr. K. Vernon Bailey is probably aware that a wheeled stretcher carrier was in use by the British Army during the South African campaign, 1899–1902, but not exactly of the same type, as the wheels were much larger and shod with solid rubber tyres. I have vivid recollections of being transported on such a wheeled stretcher across the veldt and over the railway line in Natal in 1900. I always found it most useful in moving patients and also equipment.

Wheeled Stretcher for Resuscitation

Surg. Lieut. J. C. BULSTRODE, R.N.V.R., writes: I was impressed by the suitability of the wheeled stretcher described by Dr. K. Vernon Bailey (May 1, p. 542) for use in Dr. F. C. Eve's method of resuscitation of the apparently drowned (May 1, p. 535). The provision of a stretcher of this type, preferably to carry one patient, would be of great value not only for transporting injured in dockyards where railway lines and other obstructions are common but also for the early institution of Eve's method of resuscitation. The treatment of the apparently drowned could be commenced at the dockside by Schäfer's method. On arrival of the stretcher, equipped with blankets and webbing straps for the wrists and ankles, the patient could be transferred to it and rocking started. There is no reason why the loaded stretcher should not then be wheeled to the nearest shelter, whilst rocking is continued, thus minimizing shock due to exposure.

Interstitial Emphysema of the Hand

Dr. R. JOHN GOURLAY (Menston) writes: One evening a patient aged 55 came to my surgery complaining of swelling of the left hand. That morning, while breaking up some lumps of salt with a sharp-pointed knife, she had inflicted a wound on the dorsal aspect of the thenar space. The wound was clean and 1/4 inch long. The back of the hand was considerably swollen, but not red; there was no pain and no sign of infection. On palpating the swelling fine crepitations were felt on the back of the hand and on the back of the first two fingers as far up as the first joint. On tapping the palm of the hand with my finger a hollow sound was produced. Gently I compressed the swelling towards the wound, and had the satisfaction of hearing distinctly the sound of air escaping. A clean dressing was applied to the wound and the patient made an uneventful recovery. It would appear that, owing to the oblique direction of the wound, a valvular mechanism had been instituted which, on movement of the thumb and forefinger, had caused air to be drawn into the subcutaneous tissues of the hand.

Disclaimer

Miss IDA MANN, D.Sc., F.R.C.S., wishes to state that certain irresponsible articles in the Press have mentioned her name (particularly an evening newspaper on June 4) and that this was done without her knowledge or consent.

LONDON SATURDAY JUNE 19 1943

PRINCIPLES OF EXERCISE THERAPY

BY

ERNEST A. NICOLL, M.D., B.Ch., F.R.C.S.Ed.

Surgical Director, Accident Service, Mansfield General Hospital; Surgeon-in-Charge, Miners' Rehabilitation Centre, Berry Hill Hall

Remedial exercises have long been recognized as the basis of functional recovery in fractures and other injuries of the locomotor system. In fact, the success of any accident service depends very largely on its organization for the application of therapeutic exercise to all cases and at all stages. In nearly all prolonged or serious illness, however, both medical and surgical, and non-traumatic as well as traumatic, there is a general deterioration of the locomotor system, and this is the chief cause of incapacity during the convalescent stage. In the past, convalescence from these conditions has been entirely negative and loosely supervised, but efforts are now being made by the Ministry of Health to substitute a more positive approach on the lines of the after-care organization in accident services. This, it is hoped, will be brought about by the more extended use of therapeutic exercise, on both a prophylactic and a curative basis. It should be a relatively easy proposition if the right type of organization can be evolved, because it is well known that deterioration of the locomotor system through simple disuse or toxaemia is much easier to cure than the same deterioration following trauma.

Two conditions, however, are essential to success. First, organization is necessary. The benefits of exercise therapy must be brought to all cases at the right time, in the right dosage, and in the appropriate form. Secondly, the physicians and surgeons themselves must appreciate and understand the basic principles of exercise therapy; for only then can they be expected to direct its application and to supervise intelligently the work of their technical assistants—the physiotherapist, the occupational therapist, and the gymnast. It is a defect in medical education that there is practically no teaching in this important branch of therapy, and even our most up-to-date textbooks do little more than advise us to use it. The object of this paper is to formulate such basic principles, for this is all that is required in order to direct the work of technical assistants. The busy specialist cannot be expected to acquire a detailed knowledge of remedial exercises, occupational therapy, gymnastics, recreational therapy, and the like; nor is this necessary. The experience out of which this paper is compiled was gained in directing the work of an accident service—and particularly the work of the Miners' Rehabilitation Centre at Berry Hill Hall—so it has a particular bearing on fractures and other injuries of the locomotor system. But principles are principles, and should remain true for any extension beyond this field. It is hoped, therefore, that, while being of particular interest to those engaged in the traumatic surgery of the locomotor system, the general principles here discussed will also interest that much larger body of physicians and surgeons who are now being urged by the Ministry of Health to incorporate exercise therapy into their systems of treatment. The general principles to be discussed may be stated as follows:

Therapeutic exercise must be: (1) both specific (focal) and general; (2) administered with due regard to dosage; (3) rhythmic in regard to contraction and relaxation; (4) progressive in (*a*) range, (*b*) power, and (*c*) time; (5) variable in form—the chief forms being (*a*) medical gymnastics, (*b*) occupational therapy, and (*c*) recreational therapy.

It is beyond the scope of this paper to discuss the detailed application of these principles. Where this is done it is merely in order to exemplify the principle.

Focal and General Exercises

Specific (or focal) exercises are those which pick out some particular muscle group for selective redevelopment. This in effect means devising exercises which make the desired muscle group work as a prime mover. It may be asked why this is necessary—why, for example, cannot these muscles be developed by general activity? The answer is that in a good many cases they can, but that in such cases the result depends on any general movement in which the muscle normally takes part being performed in the normal manner. In fact, however, most patients learn more quickly how to dodge the use of inefficient or painful muscles. In other words, they learn trick movements resulting in compromises. But compromises are not desirable if the normal mechanism can be regained, so focal exercises differ from general exercises in stressing, not the end to be attained, which is functional movement, but the means whereby it is attained, which is the production of the movement by a particular muscle group acting as a prime mover.

The use of focal exercises, therefore, is of most importance in injuries of the locomotor system, for in these conditions certain muscles and joints are affected a great deal while the rest are comparatively normal. Such a situation lends itself much more readily to the development of trick movements than does a *generally* weakened locomotor system following ordinary sickness; for if the *whole* system is depressed the muscles still retain their normal *relative* action even if each muscle is itself inefficient. Trick movements, on the other hand, depend on functional inequality. All faulty gaits, for example, are trick movements acquired by a patient who is made to walk when his muscles or joints are physically incapable of producing a normal gait, and it is the duty of the surgeon to pick out the particular muscles and joints concerned and redevelop them by focal exercises in order to prevent a temporary compromise from developing into a fixed habit. From these arguments it is obvious that general exercises alone, properly supervised, will usually be sufficient for the deterioration following ordinary sickness, but that in injuries affecting specific parts of the locomotor system a combination of both general and focal exercise is necessary.

An example of the need for deliberate "focusing" in exercise technique is afforded by the quadriceps. This important muscle group is wrongly regarded as a single muscle. In fact, it behaves more like two separate muscles, the vastus internus

4302

being quite selective in its action. Extension of the knee-joint to within about 15 degrees of full movement can be brought about entirely by the rectus femoris, vastus lateralis, and vastus intermedius, under conditions of minimal stress. It is only when the stress is markedly increased, as in single-leg weight-bearing, that the vastus internus enters into this range. That is why a weak vastus internus can be "caught out" in such activities as walking up and down stairs, running, and alternate-leg skipping. On the other hand, the last 15 degrees of extension, even against minimal stresses, cannot be effected *without* the vastus internus. This latter range is so small compared with the rest, however, that a patient may appear to be extending and flexing his knee-joint most energetically and using his quadriceps most effectively, yet never really using his vastus internus at all. This explains why "quadriceps drill" in plaster casts flexed more than 15 degrees at the knee-joint results in selective wasting of the vastus internus. This excessive flexion is quite unnecessary to prevent rotation of the fragments, and all long plasters should fix the knee well within the range of the vastus internus. It also explains why quadriceps drill on a flexed Thomas splint results in the same condition. Where this is necessary, as in supracondylar and lower-third fractures of the femur, exercises should be supplemented by selective faradism and the position of the knee brought to within 15 degrees of full extension as soon as possible. If any surgeon doubts this he should have himself put up in a flexed plaster or on a flexed splint and then try to do quadriceps drill and see if he can use the vastus internus—even when it is normal. The importance of all this is that the vastus internus is the key muscle in producing the last 15 degrees of extension and stabilizing the joint in all positions. If it is inefficient a syndrome is created familiar to all orthopaedic surgeons—the joint that "gives way" under stress or sudden unexpected movement. Of the two components of the muscle, the rectus femoris group can most safely be left to take care of itself because no compensatory mechanism can be devised in its absence—but the vastus internus needs the most focal and specific treatment because it operates over such a small range that a compensatory mechanism can be evolved. Once evolved it may become a fixed habit, and general activity will confirm rather than cure it. Further wasting then occurs, leading to the paradox of progressive disuse atrophy in an active patient. So the term "quadriceps drill" should be abolished and "vastus internus drill" substituted.

It is beyond the scope of this paper to go into questions of how to evolve special exercises for the redevelopment of vastus internus or other particular muscle groups—the object is merely to underline the principle that focal exercise technique is essential in certain conditions and to give the reasoning on which this opinion is based. It is necessary at the present time to make this point for two reasons—first, because it is being represented in certain quarters that general exercises will cure everything; and, secondly, because of the revival of occupational therapy. In this form of exercise therapy focal technique has not received the attention it deserves, and is apt to be disregarded entirely or even condemned. This will be referred to later.

The need for general exercises as a part of any system is self-evident. Here the body as a whole is exercised, and the injured muscles learn to act again as fixators, synergists, and antagonists as well as prime movers. Muscles were never intended by Nature to be individualists, so exercises aimed at their selective redevelopment must always be combined with exercises aimed at co-ordinating them with the rest of the locomotor system—a process often referred to as "re-education."

The Dosage Principle

Exercise therapy has been used in the past in such small and scattered doses that it may truly be said to have been on a homoeopathic basis. Having been "discovered," however, the new danger is that it will be given in poisonous doses. It is necessary, therefore, to point out that weak muscles *can* be poisoned by overdosage with exercise. Two factors have to be considered in this connexion—first, the optimum stress under which a muscle should exercise, and, secondly, the relative duration of exercise periods and rest periods. Generally speaking, the weaker the muscle the less should be the demands made on it, both in stress and in time. At Berry Hill Hall weak muscles are never exercised against more than 25% of their "all out" efficiency, but this proportion is increased to 50% as the muscle strengthens. At the same time the exercise periods are lengthened and the rest periods shortened.

The Principle of Rhythm

All therapeutic exercises should be rhythmic. Contraction must be followed by relaxation, and the relaxation must be complete and long enough to allow normal circulatory conditions to be restored in the muscle before it begins its next contraction. A good instructor teaching his patients will be heard uttering over and over again the incantation: "Contract . . . and rest . . . contract . . . and rest." Mr. J. H. C. Colson, former superintendent at Berry Hill Hall, introduced this principle into resisted pulley-and-weight exercises by incorporating ingenious "relaxation stops" in the pulley circuits (Fig. 2). He also insisted, most rightly, on its observance in occupational therapy. For this reason carpentry—which is mostly a matter of sustained contraction—was never used to any great extent in finger cases, whereas the craft-work known as netting, which involves a regularly alternating contraction and relaxation, was used extensively. There are other reasons why carpentry, the most vaunted of all forms of occupational therapy in official quarters, is also the worst. What is the scientific basis underlying this principle? In a muscle affected by disuse or injury the circulatory and lymphatic systems are impaired. Atrophy, even in non-traumatic cases, is always associated with intramural fibrosis. In a traumatized muscle there are many additional factors producing fibrosis, and fibrosis in muscle always impairs the circulatory condition by causing obstruction to venous and lymphatic drainage. Now, muscle more than any other tissue depends on good circulatory conditions, because the products of contraction (chiefly sarcolactic acid), unless speedily carried away, act as a muscle poison, and fatigue results. So in an atrophied or fibrotic muscle it is essential to give the embarrassed circulation time to clear the breakdown products—and hence exercises should be rhythmic in character as opposed to exercises which call for sustained contractions.

The Principle of Progression

The principle of progression is one of the most important and firmly established features of the Ling system of gymnastics. But its use in remedial exercises, in which it is much more necessary, has been neglected—and the same applies even more so to occupational therapy. It is not sufficient that a muscle should be made to contract—it must contract against gradually increasing stresses, through gradually increasing ranges of movement, and over gradually increasing periods of time. It is not a matter of devising an exercise to make a muscle work; the task of the physiotherapist is to devise a whole series of exercises which provide smooth progression from the stage of extreme weakness to the stage of full use against the stresses of normal work. This progression must be in three dimensions—in range of movement, in power of movement, and in duration under stress—but by far the greatest of these is *power*. Range without power is worse than useless, for in its extreme form we have a flail-joint. Power without range, on the other hand, is compatible with full function in heavy industry. So progression in power is of absolutely vital importance in exercise therapy.

But to consider first the methods of increasing range of movement. Passive movements, at one time widely practised, are now almost universally condemned. Active movements, on the other hand, are universally recommended. But what fundamental differences are there that place them such poles apart? Surely only two factors are involved: first, that the force applied is much greater in passive movement; and, secondly, that this greater force is not under the patient's control. Now there is no reason why the force available should not be increased—in fact, this is desirable. Suppose, for example, that the patient is trying to mobilize a stiff shoulder limited in abduction, and the normal muscles available to produce this movement are wasted and weakened—as they are likely to be. Would any surgeon object if the power of those muscles were suddenly increased to normal or even a little above normal? On the contrary, he would welcome it. So the only objection to passive movement must be that this desirable extra force is provided by an outside agency—and that is, of course, a very legitimate objection. But suppose that by means of a pulley circuit (Fig. 1) the abductors of one arm are reinforced by the adductors of the opposite arm—then the extra force available for breaking down adhesions and stretching contracted tissues is still under the patient's control. This type of exercise has been developed at Berry Hill Hall for practically all the important joints of the body, and has been called "auto-assisted active movement (A.A.A.)." Even the proximal interphalangeal joints of the fingers can be mobilized in this way by strapping the stiff finger above and below the joint to its fellows on either side. The following is an example of the use of the pulley circuit.

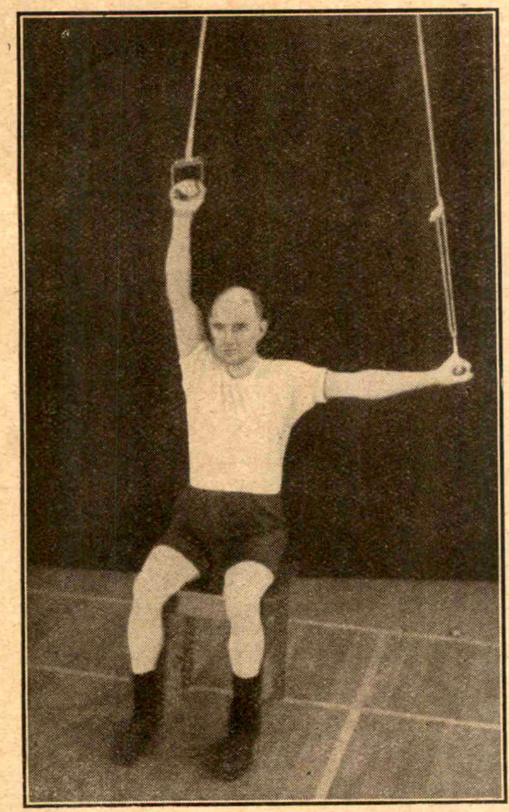

FIG. 1.—Remedial exercise with a pulley circuit for self-assisted active movement.

The patient shown in Fig. 1—a miner aged 50—sustained a severe shoulder injury which resulted in complete stiffness. At the beginning of treatment at Berry Hill Hall he had no shoulder movement at all, and was so weak he couldn't lift a bucket. It took three months' hard work to cure this most difficult case; but it was worth every minute of it, for he has regained full movement and full power, and is now back at his job as a coal-face miner.

Apart from its use in recovering movement, this type of exercise has another indication, and that is to preserve movement that would otherwise be lost through painful inhibition. To take the shoulder once more as an example—it is well known that many stiff painful shoulders result from simple contusion, and the difference in prognosis between a dislocation due to a fall on the hand without damage to the deltoid and one associated with contusion to the deltoid is equally well known. Contusion in certain muscles, of which the deltoid is one, produces severe pain when the muscle contracts under stress. To guard against this the patient elevates his arm by fixing the shoulder-joint and rotating the scapula, thus producing the familiar "reversed rhythm" seen in these cases. Painful inhibition of movement in a contused muscle leads to fibrosis; fibrosis leads to more pain, and so the vicious circle goes on till it ends as a "frozen shoulder." What was originally a painful inhibition becomes a painful contracture. There are two aims of treatment in the early stages of such a condition—to cure the pain and so release the inhibition, and to preserve the normal range of movement during this process, which may be prolonged. The best way to preserve movement in these cases is by the use of auto-assisted active exercises. Another method is by using a weight to assist the movement. This can be done on the same pulley apparatus, the weight being gradually diminished as improvement allows. Once the stress is removed the muscle is able to contract without pain, and normal rhythm and full range are restored. Strictly speaking, this is not an example of progression in range—it is a special use of exercise technique to prevent loss of range; but it embodies some very important general principles.

Progression in power is usually obtained in gymnastics by making the performer do the exercise from different gymnastic positions. In the simplest form of the exercise a position and a technique are adopted which allow the performer to obtain help from accessory muscles. In the various progressions these are cut out by degrees. Another gymnastic method of obtaining progression in power is by using the lever principle in reverse. For instance, in extension of the spine from the prone position, the arms are first kept at the sides, then clasped behind the neck, and finally fully stretched out ahead of the patient. A third method is to start by performing the exercise in "inner range" and gradually progress to "outer range" movement on the theory that all muscles have to act more powerfully in outer range.

But the most scientific way of obtaining progression in power is to add a resistance which can be accurately measured. This is achieved very simply and very effectively by the use of pulley-and-weight apparatus, the principle of which is illustrated in Fig. 2. This type of apparatus is used only for the focal type of exercise, so it is essential to isolate the muscle effectively as a prime mover. The "relaxation stop," mentioned earlier, is a knot or metal runner in the cord arranged in such a way that it engages in the pulley and takes the entire strain of the weight in the resting position of the exercise.

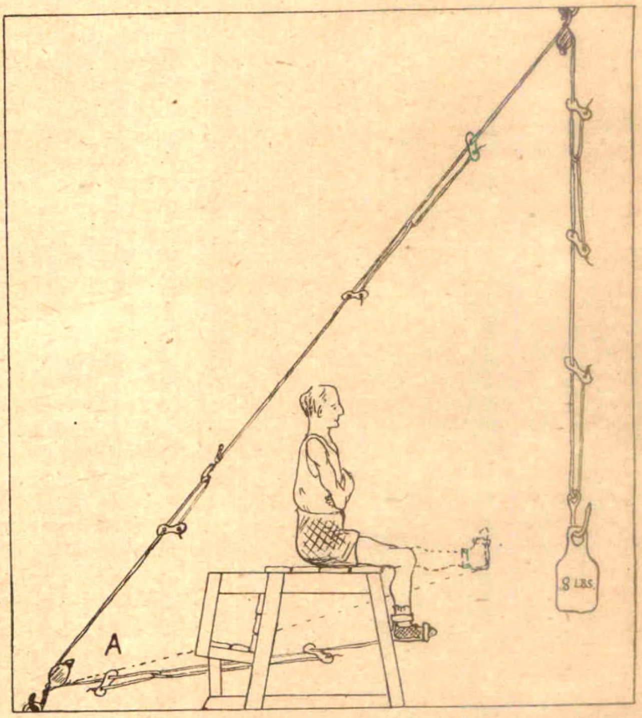

FIG. 2.—The principle of the calibrated resistance exercise (A = relaxation stop).

It is extremely important in using this type of exercise to pay due regard to the dosage principle. Failure to do this has produced chronic sprains, especially in knee cases, and has led several surgeons to issue warnings against the use of resisted exercises altogether for the knee. This is quite wrong, because the principle of progression in power is unchallengeable, and the apparatus evolved to achieve it is beyond criticism. The fault lies in the use of the method without due regard to the dosage and relaxation principles. At Berry Hill Hall no ill effects have been observed when using the technique described earlier in discussing dosage. Another way to produce sprains in knee cases is by failing to redevelop the vastus internus and then making it work against the same resistance as the rectus femoris component. This in its turn is due to failure to recognize the vastus internus as a separate muscle and therefore to use the entirely separate pulley circuit appropriate to its action.

The third type of progression in exercise therapy is progression in time—that is, carrying out the exercise under the same stress for increasing periods. This is very important in rehabilitating industrial workers, because industry demands not only that a workman shall be able to exercise his muscles against certain stresses but that he shall be able to do so continuously for whatever number of hours constitutes a "shift."

Principle of Variation in Form

If exercise therapy is to be carried out for many hours a day it must be disguised in various forms to make it palatable to the patient. Medical gymnastics alone would become boring; the patient would lose interest and initiative, and therefore cease to put his best endeavours behind them. So exercise therapy must be capable of assuming different forms, though in doing so it must conform as nearly as possible to the general principles already laid down. Unfortunately this is not always the case, and in the two chief disguises—occupational therapy and recreational therapy—the art of "sugar-coating" the pill has proved so diverting that the ingredients of the pill itself have been rather overlooked. Another reason why there must be variation in form is that medical gymnastics do not lend themselves to certain conditions. For example, no patient would sit in a gymnasium flexing and extending his fingers for six hours a day, but he will do it in an occupational-therapy department.

It is beyond the scope of this paper to discuss either occupational therapy or recreational therapy, but there are a few points in regard to both that bear on principles. Occupational therapy is used, of course, in two quite different ways—as a mental diversion (with which this paper is not concerned) and as a disguised form of remedial exercise. Employed in the latter sense, it becomes more important than ever to ensure that the proper muscles and joints are used, and that the patient is not simply learning trick movements. This can often be achieved by fixing the compensatory joints in plaster—e.g., in netting by fixing the metacarpo-phalangeal joints in order to make the patient use his proximal interphalangeal joints. Forms of craftwork should be favoured in which the movements are an alternate contraction and relaxation, such as weaving; those involving impaction stresses and sustained contraction should be avoided. Progression in range and power should not be lost sight of, and with ingenuity both can be incorporated into most forms of occupational therapy. For example, looms have been designed at Berry Hill Hall for shoulder, forearm, wrist, knee, and ankle movements, each with its own mechanism for ensuring effective muscle isolation and progression in both range and power.

The chief aim of the surgeon in all this should be not to acquire a detailed knowledge of occupational therapy but to satisfy himself that the essential principles of therapeutic exercise are being satisfied. Very little need be said about recreational therapy. It is a form of general exercise in which some sort of rough progression is possible, as, for example, in progressing from simple sitting games to walking and then running games. Games can never be very specific, nor is it desirable that they should be; their chief role is to redevelop general bodily function in a psychologically stimulating atmosphere, and the principal concern of the surgeon will be to protect his patients against the possible ill effects of their own enthusiasm or that of their fellows.

Summary

The basic principles of exercise therapy have been discussed and the following five requirements laid down:

(1) Exercises must be both focal and general. (2) They must be administered with due regard to correct dosage. This is variable from case to case and at different stages in the same case. (3) They must be rhythmic in character. (4) They must be progressive in range, power, and time. (5) They must be variable in form, the chief forms being gymnastic, occupational, and recreational.

It is considered that a knowledge of these principles is all that is required or can be expected of the surgeon or physician who has to incorporate exercise therapy into his system of treatment. The detailed application and elaboration of principles is the province of the technical assistants in the various forms of exercise therapy.

JAUNDICE FOLLOWING ADMINISTRATION OF HUMAN BLOOD PRODUCTS

BY

H. V. MORGAN, M.B., M.R.C.P.
Physician, E.M.S.; Chief Assistant to the Medical Professorial Unit, St. Bartholomew's Hospital

AND

D. A. J. WILLIAMSON, M.B., B.S.
Surgeon Lieutenant, R.N.V.R.; Late Chief Assistant, St. Bartholomew's Hospital

At the present time human blood and its derivatives are being widely used for transfusion purposes. It therefore seems relevant to describe a small series of cases of jaundice which have followed the intravenous administration of plasma or reconstituted dried human serum.

Summary of Literature

Findlay and MacCallum (1937, 1938; with Murgatroyd, 1939) reported the occurrence of 89 cases clinically resembling infective hepatitis among 3,100 persons inoculated against yellow fever from 36 days to 7 months previously. The vaccine consisted of yellow fever virus suspended in human serum, which was obtained at first from patients who had recovered from yellow fever, but latterly from healthy donors without a past history of jaundice. The volume of serum injected in each case never exceeded 0.275 c.cm. These observers clearly demonstrated that the disease was not a form of yellow fever, and suggested that it was due to a hepatotoxic virus in the serum. Soper and Smith (1938) and Fox *et al.* (1942) recorded similar cases in South America.

A widespread outbreak has recently occurred among members of the American Forces inoculated against yellow fever (Memorandum on Yellow Fever Jaundice, 1942). 28,585 cases were reported during the first half of 1942, 62 of which were fatal. The clinical condition, which again resembled "catarrhal jaundice" except for the occurrence of joint pains and urticaria in 20% of cases, developed 40 to 120 days after inoculation. Necropsy showed acute or subacute necrosis of the liver, sometimes associated with nodular hyperplasia. Of particular interest is the complete absence of contact cases.

MacNalty (1937) reported 37 cases of acute infective jaundice, with seven deaths from acute hepatic necrosis, occurring 16 to 100 days after the administration of convalescent measles serum. All the 37 cases were from a group of 82 to 109 persons inoculated with serum of a particular batch. Propert (1938) in describing seven of these cases of infective hepatitis mentioned the occurrence of jaundice in two uninoculated children who two months previously had been in contact with some of the cases. Findlay and MacCallum quote several observers who have reported cases of hepatitis occurring in horses after inoculation against a number of equine diseases. The only common constituent of the inocula was horse serum (Theiler, 1919; Gordon, 1935; Marsh, 1937; Slagsvold, 1938).

Clinical Material

Late in May, 1942, an atypical case of jaundice occurred at an E.M.S. hospital (Case 3). A fortnight later a patient discharged from this same hospital (Case 4) was admitted to an associated hospital with a similar clinical condition. Comparison of the two cases showed that both had received intravenous serum several weeks previously. It was therefore felt that these might be examples of the type of jaundice caused by the administration of serum. An investigation of all cases known to have been transfused with serum or plasma in the past year was begun, and the following results were obtained.

During the period Aug., 1941, to June, 1942, 56 patients at the two associated hospitals are known to have had transfusions of liquid pooled plasma or reconstituted dried human serum. The majority of these were suffering either from peripheral vascular disease (Hayward, 1942) or from disorders associated with low plasma protein concentration. Most of the patients were otherwise in good general health at the time of transfusion and none was acutely ill. Their ages ranged from 15 to 78 years, though most were between 40 and 70. Of the cases which developed jaundice all but one (Case 8) were transfused at the sector hospital. The quantity of fluid transfused varied from 300 c.cm. to 6 litres, usually given in weekly amounts of 800 c.cm. Reactions consisting of pain in the back, vomiting, rigors, and pyrexia were not infrequently noted at the time of administration, but there was no obvious relation between the severity of the reaction and the occurrence of jaundice. The serum, which was obtained from the Medical Research Council, was prepared for use in the following manner:

The bottles of dried serum and of freshly distilled water were warmed to 37° C. in a water-bath. 200 c.cm. of the distilled water was then added to each bottle, which was gently shaken until all the serum had dissolved. The serum was thus reconstituted in normal strength and was administered through a Medical Research Council transfusion outfit.

Of the 56 patients, 50 have been traced, and 9 (18%) of them have since developed jaundice. Six of these cases were under our direct observation at the time of jaundice, but three (Cases 1, 2, and 8) were questioned retrospectively.

Case Reports

Case 1.—Railway signalman aged 59. Intermittent claudication and gangrene of toes due to degenerative vascular disease. Dec. 1 to Dec. 11, 1941: Three transfusions, each of 1,080 c.cm. of plasma. Dec. 23, 1941, to Jan. 9, 1942: Amputation of toes and then of leg under nitrous-oxide–oxygen–ether anaesthesia, followed by removal of dressing with trichlorethylene analgesia (inhalation of only 1 c.cm.). The wound was dressed with sulphanilamide powder. Feb. 7: Discharged to his home, where he had no known contact with any case of jaundice. Early in March, 1942 (approximately 90 to 100 days later): His wife noticed yellowness of sclera. Simultaneous onset of lassitude and anorexia; no rigors or sweating; no abdominal discomfort or vomiting. He was constipated, passing "white" stools and dark urine. No rash, no joint pains, no bruising. His condition remained unchanged for five to six weeks, when his symptoms cleared except for the jaundice, which persisted for a further month. There were no contact cases among his family or friends.

Case 2.—Labourer aged 41. Spondylolisthesis. Feb. 16, 1942: Transfused with 800 c.cm. serum. May 9 (82 days later), malaise. May 10: Developed abdominal discomfort and jaundice with dark urine and clay-coloured stools; diagnosed by his doctor as severe "catarrhal jaundice." June 5: Able to return to work, although the jaundice and abdominal discomfort persisted for a further four or five weeks.

Case 3.—Tool-maker aged 51. Intermittent claudication due to degenerative vascular disease; indolent plaster sore. Jan 29 to March 17, 1942: Six weekly transfusions of serum, each of 800 c.cm. Plaster sore dressed with sulphanilamide powder. May 24 (68 to 115 days later): Generalized erythema and minutely papular rash on trunk and limbs. The rash, which lasted for three days, was not irritant and did not affect the head and neck. May 25: Progressive rise of evening temperature to a maximum of 103.2° F. on May 31, when the patient was noticed to be yellow. June 1: Jaundice deeper; liver palpable three fingerbreadths below the costal margin, and tender. Spleen impalpable. Urine contained bile pigments but not bile salts. Stools pale but not clay-coloured. W.B.C., 5,200 per c.mm. Blood sulphanilamide concentration too low to estimate. Serum van den Bergh reaction: Direct, positive in 2 minutes; indirect, 12 units. No abdominal symptoms. The temperature subsided during the next six days, but the jaundice disappeared more gradually. June 14: W.B.C., 8,200 per c.mm.—polymorphs 4,675, basophils 40, eosinophils 165, lymphocytes 2,910, monocytes 410. June 19: Liver impalpable; urine bile-free. Has remained well since. With the onset of jaundice there was a marked improvement in the rate of healing of his ulcer. Agglutination of *Leptospira icterohaemorrhagiae* negative. Blood Wassermann reaction negative.

Case 4.—Engineer aged 62. Intermittent claudication due to degenerative vascular disease. April 20, 1942: Transfused with 800 c.cm. serum. June 8 (49 days later): Malaise, anorexia, and abdominal discomfort lasting for three days. June 10: Noticed to be jaundiced. June 12: Admitted to hospital. Definitely jaundiced, with enlarged tender liver two fingerbreadths below costal margin. Spleen impalpable; urine contained bile pigments; and the stools were pale. Except for temperature of 100° F. on the first day he remained apyrexial. June 17: W.B.C., 13,400 per c.mm.—polymorphs 9,510, basophils 130, lymphocytes 2,550, monocytes 1,210. Van den Bergh reaction: Direct, positive in 20 seconds; indirect, 6 units. June 22: Passed three loose melaena stools. The depth of jaundice fluctuated but improved. July 19: Discharged with liver just palpable. Aug. 4: Still slightly jaundiced and liver still palpable. Sept. 21: Free from jaundice; liver impalpable.

Case 5.—Cabinet-maker aged 62. Intermittent claudication due to degenerative vascular disease. March 5 to 26, 1942: Four weekly transfusions of serum, each of 800 c.cm. June 16 (82 to 103 days later): Malaise and anorexia for one week. June 22: Epigastric discomfort and dark urine. June 29: Admitted to hospital apyrexial and definitely jaundiced, with a large tender liver two fingerbreadths below costal margin. Spleen impalpable; stools pale; urine contained bile pigments. Tourniquet test positive. July 1: W.B.C., 4,200 per c.mm. Van den Bergh reaction: Direct, positive in 10 seconds; indirect, 10.5 units. July 9: More deeply jaundiced. Liver enlarged to three fingerbreadths and very tender. Spleen just palpable. Depth of jaundice varied, but gradually lessened. Aug. 10: Liver two fingerbreadths and tender. Spleen still palpable. Takata-Ara weak positive. W.B.C., 5,000 per c.mm. Sept. 5: Discharged with slight jaundice and a liver which was just palpable

Case 6.—Publican aged 57. Intermittent claudication due to thrombo-angiitis obliterans. Sept. 8 to Oct. 7, 1941: Four transfusions of serum, each of 800 c.cm. Feb. 12 to April 1, 1942: Four transfusions of serum, each of 800 c.cm. June 27 (87 to 135, or 245 to 274 days later): Became jaundiced. Symptom-free and apyrexial apart from a rise in temperature to 99° F. on one evening. Liver and spleen impalpable; urine contained bile pigments; stools remained normal in colour. W.B.C., 17,000 per c.mm.—polymorphs 8,670, eosinophils 170, basophils 85, lymphocytes 6,205, monocytes 1,870. The patient's jaundice gradually subsided in the next three weeks. Blood Wassermann reaction negative. Agglutination of *L. icterohaemorrhagiae* negative.

Case 7.—Male aged 59; messenger. Diabetes mellitus with gangrene of toes. March 11 to May 7, 1942: Six transfusions, five of 800 c.cm. of serum and one of 1,080 c.cm. of plasma. July 20 (74 to 131 days later): Epigastric discomfort and flatulence for a few days; jaundice with tender enlarged liver three fingerbreadths below costal margin; apyrexial; urine contained bile pigments; stools pale. Aug. 2: Van den Bergh reaction: Direct, positive in 30 seconds; indirect, 7.5 units. Aug. 12: Discharged from hospital feeling well, with only slight jaundice; urine free from bile.

Case 8.—Female aged 45; secretary. Calcinosis circumscripta. May 16, 1941: Transfused with 300 c.cm. of serum July 22 (67 days later): Anorexia, malaise, feverishness, and dark urine; pale stools. Aug. 5: Jaundice confirmed by her own doctor; this persisted for about 6 weeks.

Case 9.—Traveller aged 31. Intermittent claudication due to thrombo-angiitis obliterans. June 2 to 18, 1942: Three transfusions of serum, each of 800 c.cm. Oct. 1: Lumbar sympathectomy performed under nitrous-oxide–oxygen–ether anaesthesia; followed by pyrexia up to 100.8° F. for 24 hours. Oct. 3 (107 to 123 days later) Nausea, which lasted for a few days, and gradually increasing jaundice; liver enlarged; spleen impalpable; urine contained bile pigments; stools, normal in colour, contained no occult blood; apyrexial. Oct. 5: Blood van den Bergh reaction: Direct, immediate positive; indirect, 12.5 units. W.B.C., 8,900 per c.mm.—polymorphs 6,230, eosinophils 180, lymphocytes 2,135, monocytes 355. The jaundice gradually subsided in the next three weeks. Blood Wassermann reaction negative. Agglutination of *L. icterohaemorrhagiae* negative.

Epidemiology

Of these cases all but one (Case 8) were transfused in the sector hospital. There were no cases of infective hepatitis among patients in the wards of this hospital during the significant period. Although three nurses developed infective hepatitis during this period of seven months, they were working elsewhere in the hospital, and at no time had contact with the cases described. There were no cases of jaundice among the medical and nursing staffs of the wards concerned. All the patients who returned to their homes before developing hepatitis denied contact with any case of jaundice. The cases were distributed throughout four wards, and significant contact between them while they were jaundiced occurred in only one instance. Case 6 was in Ward MG1, and not confined to bed during the whole period in which Case 3 was jaundiced. He himself developed jaundice five weeks after the onset of prodromal symptoms in Case 3. There were 32 other patients in the ward at this time; of these only one (Case 9) has developed jaundice, and he only after an interval of three and a half months.

No other cases of jaundice have come to our notice among persons in contact with our patients.

Clinical Picture

The clinical features of these cases are summarized in the accompanying table. The onset of symptoms, which was sudden, occurred 49 to 107 days after the last transfusion. Jaundice, which appeared at the onset of the illness in five cases, was intense in some patients, and often varied in degree from day to day. Malaise, nausea, and epigastric discomfort, which sometimes persisted for some weeks, accompanied the jaundice in seven cases and preceded its onset by a few days in three. In only one case (Case 3) was a rash observed: it preceded the onset of jaundice by eight days. None of our patients complained of joint pains or biliary colic. In all but one of the cases we examined the liver was enlarged and tender; but in only one (Case 5) was the spleen palpable. In no case was ascites demonstrated. There was a positive direct van den Bergh reaction in five cases and unduly pale stools in seven. The severity of the illness, which bore no relation to the volume of fluid transfused, varied from the symptomless jaundice of Case 6 to the severe illness with intestinal haemorrhage of Case 4. On the whole the cases were of moderate severity, and only Case 4 gave rise to anxiety. The duration of the illness varied from 3 to 12 weeks.

Summary of Cases

Case	Age and Sex	Amount of Serum or Plasma (c.cm.)	Symptomless Period in Days	Symptoms and Signs									Pathological Investiga			
				Onset of Jaundice (Day of Disease)	Malaise, Nausea, and Abdominal Discomfort	Rash	Pyrexia	Liver Enlargement in F.B.s	Spleen	Stools	Melaena	Duration in Weeks	Total W.B.C. per c.mm.	Direct van den Bergh	Indirect (units)	W.R.
1	59, M.	3,240 plasma	90–100 approx.	1st	Present several weeks	—				" White "		10				
2	41, M.	800 serum	82	2nd	Present several weeks	—				Clay-coloured		8–9				
3	51, M.	4,800 serum	68–115	8th	—	+	Up to 103° F. 1st fortnight	3 F.B.s. Tender	—	Pale		4	5,200	+	12	—
4	62, M.	800 serum	49	3rd	Present three days	—	100° F. on 1st day	2 F.B s. Tender	—	Clay-coloured at times	+	7½	13,400	+	6	
5	62, M.	3,200 serum	82–103	7th	Present one week	—	—	3 F.B s. Tender	+	Pale		12	4,200	+	10·5	
6	57, M.	3,200 + 3,200 serum	87–135 or 245–274	1st	—	—	99° F. on 1st day	—	—	Normal		3	17,000			—
7	59, M.	4,000 serum + 1,080 plasma	74–131	1st	Present a few days	—	—	3 F.B.s. Tender	–	Pale		3½		+	7·5

9	31, M.	2,400 serum	107–123	1st	Present a few days	—	Post-oper. only	3 F.B.s	—	Normal		3	8,900	+	12·5	—

Diagnosis

The clinical picture, though showing considerable variation, most closely resembles that of infective hepatitis as described by Cullinan (1939); it does, however, differ in the following respects:

(1) Our patients belong to a considerably older age group than that usually affected (Newman, 1940; Norton, 1939), although Pickles (1939) states that infective hepatitis is not uncommon among older people. Fox *et al.*, in describing an outbreak of jaundice following yellow fever inoculation, report a significantly higher incidence among the older age groups. (2) The illness was, on the average, of greater severity and more protracted. (3) In only one (Case 6) was there a history of contact with a possible source of infection. (4) No cases of jaundice have been reported among persons in contact with our patients.

We were not led to expect a subacute necrosis due to any of the better-known hepatotoxic chemicals. The absence of relapses in our patients is also against this diagnosis.

The clinical picture of our cases does not resemble spirochaetosis icterohaemorrhagica: there was no albuminuria or marked polymorphonuclear leucocytosis, and the serum from three cases gave negative agglutination reactions.

Discussion

From the clinical and epidemiological evidence it seems unlikely that this is a straightforward outbreak of infective hepatitis. These were the only cases of hepatitis in the hospital
at the time, and the only common causal factor
administration of serum or plasma. It therefore seems
that these fluids are of aetiological significance and
outbreak is similar to those occurring after yellow f
measles inoculation. Our cases differ, however, in
were given relatively large quantities (300 to 6,400 c.c
venously, compared with very small amounts (0.2
intramuscularly. Most of our patients, too, were k
be suffering from arteriosclerosis, and might conceiv
had some liver change, rendering them more susc
hepatotoxic agents. In two of the cases, however,
no evidence of vascular disease.

There are three main possibilities as to the part
the serum in the production of jaundice:

1. Hypersensitivity Reaction.—There was no direct
in favour of this view: our patients did not give
of allergy and showed no eosinophilia. The time re
would appear to be too long for an anaphylactic
reaction.

2. Introduction of a Hepatotoxic Agent.—In son
recorded outbreaks there has been evidence that on
batches of serum have been hepatotoxic. In our se
paratively few of the batch numbers are available, an
two cases (4 and 9) do we know all the numbers c
In these two cases there was one common batch (
which was also administered to Case 7. Serum from
was given to at least two other patients, who did nc
jaundice. Batch 120 KY was derived from a pool o
of serum, a contribution of 250 donors, whom it
possible to trace. It is probable that Case 8 did
serum from this batch, and Case 1 was transfused
plasma. There is therefore no evidence of an ab
confined to one batch of serum. If a hepatotoxic
been introduced it must be one which is commor
dried serum and liquid pooled plasma. It might b
virus contained in the fluid, as suggested by Fir
MacCallum, or some toxic chemical substance such,
plasma protein. In our series there is no evidence
one or other of these hypotheses.

3. Increased Liver Susceptibility.—Certain agents
neoarsphenamine (Stokes, Reudemann, and Lemon,
acriflavine (Murray, 1930), are believed to reduce the
of the liver, rendering it more susceptible to the
infective hepatitis. It is possible that our cases re
outbreak of this disease, with the serum acting as a t
but this seems unlikely in view of the lack of infec
the long symptomless period.

Summary

Nine cases of jaundice are described which develope
weeks after transfusion with serum and plasma, a
resembled the hepatitis following inoculation against y
and measles.

The association of such cases of jaundice with transfusion may easily be overlooked in view of the long symptomless period which intervenes.

We wish to thank various members of the staff of St. Bartholomew's Hospital for permission to publish the cases under their care, and gratefully acknowledge the helpful criticism of Dr. A. E. Gow, Prof. Ronald V. Christie, and Dr. Hugh Barber.

A NEW AND SIMPLE METHOD FOR SUBCUTANEOUS LIGATURE OF VARICOSE VEINS

BY

B. W. GOLDSTONE, M.B., B.Sc., F.R.C.S.Ed.
Major, R.A.M.C.

The injection of various solutions into varicose veins often causes their obliteration; but this technique is generally useless when the upper part of the great saphenous vein is varicose: the downward pressure of this long column of blood unfortunately unseals the attempt at thrombosis.

In the past decade surgical opinion has recognized this factor, and operations for high ligature of the vein have become standardized. These are usually, and rightly, combined with injection of the vein's lower reaches. This combined operation is generally very successful. Lately, several surgeons have practised a still simpler technique: the vein is compressed subcutaneously instead of by open operation. I use the word "compressed" advisedly, as will appear later from the text, although these others refer to their methods as ligature. By this technique a curved needle is thrust into the skin at the side of the vein; it passes deep to the vessel and reappears at the other side of it. The two free ends are then tied over a pad of gauze. Below this the varicosities of the lower leg are injected.

I find that there are several marked advantages in these subcutaneous methods, particularly from a military point of view. First, there are a large number of men who obstinately refuse to be "cut about." When it is explained to them that the cure (I carefully avoid the word "operation") entails absolutely no cutting, they then find that they can furnish no adequate reason against being cured. Also, the method, being ambulatory, effects a great saving in hospital beds. With an open operation, even after the patient leaves the ward, he must remain relatively immobile until the wound has healed strongly. The use of the subcutaneous operation should result in raising thousands of soldiers into a higher category.

The method hitherto used is described as subcutaneous ligature. It is certainly subcutaneous, but it is a unilateral compression, not a ligature. A true ligature should evenly compress the vein's entire circumference towards its centre. A much more effective and permanent result is likely to follow from a true ligature. The simple method described below forms a true ligature around the vein. In addition the little operation is complete at one sitting. Patients need not return to the clinic for removal of stitches. Usually I tell them to return, but it is more for my interest than in theirs.

Method

The patient stands and the highest visible part of the internal saphenous vein in the thigh is shown; but it is advisable to keep at least 2 in. below the saphenous opening. A local anaesthetic wheal is raised on each side of the vein. A curved cutting needle is then threaded with catgut. It is plunged into one wheal, passes deep to the vein, and emerges through the skin via the opposite wheal (Fig. 1). This curved needle (Fig. 2) is now removed from the catgut and a straight needle substituted on to the catgut. This straight needle is now thrust back into the skin *via the same minute opening* through which the curved needle has recently emerged. The straight needle passes in front of the vein and emerges through the same minute hole where the curved needle made its original entry (Fig. 3).

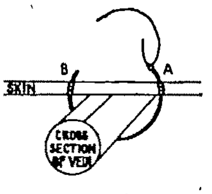

FIG. 1

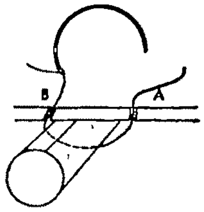

FIG. 2

FIG. 1.—Stage I: Curved needle passes through skin, then deep to vein, to emerge through skin at opposite side. Thus the two skin punctures A and B are made.

FIG. 2.—Stage II: Curved needle has emerged. A straight needle must now be substituted on to the catgut.

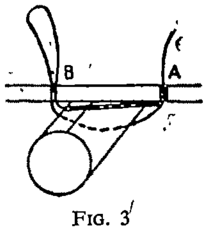

FIG. 3

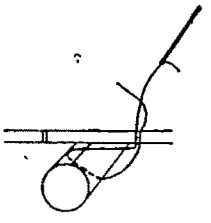

FIG. 4

FIG. 3.—Stage III: Straight needle has re-entered skin via B and is about to emerge via A. Here needle passes in front of vein.

FIG. 4.—Stage IV: Straight needle has emerged and the two original ends of the catgut are ready to be tied together with a reef-knot, forming a true ligature around the vein.

The two ends of the catgut are once more in juxtaposition (Fig. 4); they are tied fairly tightly and cut short; the knot retracts and almost disappears. The little operation is complete It is extremely simple to do; in fact, reading about it demands more effort than actually doing it. The area receives no dressing other than a small piece of bare elastoplast. This is removed in one week, when the catgut knot will have disappeared spontaneously. There will now be a minute puncture and the surrounding skin will have a slightly traumatized appearance, but no further treatment is necessary; in a short time the skin regains its normal appearance and elasticity.

A few days after the original ligation the varicose veins below the knee should receive one or more injections as necessary, but great caution should be observed; only a small quantity of the thrombogenetic fluid should be injected at first (1 c.cm. of 5% sodium morrhuate would be a good initial or test dose). The reason for this cautious and small injection is obvious: with the main internal saphenous vein ligatured the venous current is so slow that dilution or washing away of the chemical hardly occurs; from a minimal dose maximal results are obtained.

For a week after the ligation patients can move about and are quite fit for light duties. After that they rapidly become normal.

Discussion

For the past few months I have carried out this simple procedure on every suitable case that has come under my care, the results being invariably successful. I must admit that as yet I have had no large series of cases. The procedure is so simple that I have already begun to ligate the larger varicosities of the lower leg in preference to their injection, though care is exercised in avoiding flexures.

Many surgeons have objected to any ligation of the saphenous vein short of its junction with the femoral vein. Some have even stressed the necessity for ligating the small tributaries (superficial epigastric, etc.) that flow into the vein at this level. In spite of these theoretical objections there is no doubt that ligation at a low level is effective. Is it permanent? Possibly not, but this slight procedure is so rapid and easy for both surgeon and patient that it is certainly worth doing, even though no lifetime guarantee is attached. In any case, we are living in times when it is probably wise to follow a short-term policy in such matters. If we can bring a man, and more especially a soldier, into a higher category for the duration of the war it is worth while.

Summary

A new and simple method is described for the complete subcutaneous ligature of varicose internal saphenous veins. It has the advantage that the operative treatment is complete at one sitting and that no incision is necessary. The treatment is ambulatory.

POST-OPERATIVE RESPIRATORY COMPLICATIONS IN SERVICE CASES

BY

H. MARCUS BIRD, M.R.C.S., D.A.

S. D. KILNER, M.D., D.M.R.E.

AND

DERRICK J. MARTIN, F.R.C.S.Ed.

Being struck by the high incidence of post-operative respiratory complications in Service cases as compared with those occurring in civilians, and noting that Kaye (1941) and Binning (1940) have described similar experiences, we decided to keep a record of a series of consecutive cases in an attempt to find some causative factor.

A record was kept of the age, operation, premedication, type and amount of anaesthetic, duration of anaesthesia, any unusual incident during anaesthesia, and any post-operative complications in a series of consecutive cases undergoing surgical procedures at an E.M.S. hospital. The patients were all members of H.M. Forces, the great majority of them anaesthetic-resistant subjects in the "pink" of physical condition. Many of them had that type of "dust and tobacco pharyngitis" described by Kaye (1941). The wards were remote from the operating theatre, necessitating a journey in the open air to and from the theatre.

Clinical

The cases developing post-operative respiratory complications all followed a very similar course. The temperature rose on the second, third, or fourth day to a point between 100° and 102° F., with cough and purulent sputum. All had moist sounds in the chest, which were usually most noticeable at the base on the side operated on. The signs were those of a simple bronchitis, and only three had signs of consolidation. If the temperature rose above 101° F. sulphapyridine was given; but the course did not seem to be materially altered by this, for in four days from the onset of symptoms most of them had settled down to normal, the sputum had become very scanty, and what there was of it was colourless and frothy.

All patients were operated on at the earliest opportunity, the majority on the day after admission, so that the risk of their getting any infection in the ward was reduced to a minimum. Most of them were smoking heavily up to the time of operation, and at one time, from February to April, all patients operated on for hernias and appendicitis were forbidden to smoke till after the fourth day. It was not found that stopping smoking after operation had any effect upon the incidence of complications, and non-smokers were affected as well as smokers.

It was soon apparent clinically that the power to cough and to breathe deeply were factors, and we began to institute measures to encourage free movements and deep breathing. For the 24 hours after operation all men operated on for abdominal conditions were given inhalations of carbogen for ten minutes every two hours when awake. This did not make any difference that we could detect. We then began to get all these cases out of bed the day after operation; from the second day they stayed up longer, and were encouraged to walk if they wanted to. This procedure was continued even when the temperature rose, as the men soon found that they were able to cough much more easily when sitting in a chair than when propped up in bed. This routine was adopted after a personal communication from Lawrence Abel. On the first day the patients move out of bed rather unwillingly, on the second day they are quite willing to sit by the fire, and on the third or fourth they begin to walk about the ward and to go to the lavatory of their own free will. This has not lessened the incidence of complications, but it has diminished the time taken for recovery and has possibly been a factor in the avoidance of a real pneumonia. Before we started getting these cases up three men developed consolidation, but since that time we have had only one case, to be described later. When treated in this way the cough made no difference to the man's rate of recovery, for after four days he seemed none the worse, and was transferred to a convalescent home on the eighth day.

[The final end-results of the operations for hernia, which at present seem most satisfactory, will, it is hoped, be the subject of a later communication.—D. J. M.]

Throughout this series a critical attitude has been adopted as to what constitutes a chest complication. Any cough, even without rise of temperature or without sputum, has been recorded. As it was found that some house-surgeons were more critical in their attitude than others, the latter part of the investigation was entrusted to one person who made regular ward rounds, with the post-operative condition of patients as the sole object.

Deaths.—In this series there has been no death solely attributable to anaesthesia, but one case in which the patient died should be noted. He was admitted with a paralytic ileus, and an ileostomy was performed under nitrous-oxide–oxygen–ether anaesthesia. He had a continuous intravenous glucose-saline for eight days. No pulmonary symptoms developed. Twenty days later the ileostomy was resected under nitrous-oxide–oxygen–trilene–ether anaesthesia and the abdomen closed. After the second operation he was gravely ill, and among other symptoms developed a pneumonia which did not resolve, and he died 84 days later. Necropsy showed a number of small lung abscesses and a local peritonitis.

Complications after Various Operations

Out of 2,000 consecutive cases undergoing surgical procedures under anaesthesia, 101 had post-operative temperatures of over 100° F. with cough and sputum, and 46 developed post-operative cough with no rise in temperature. It soon became obvious that the type of operation and not the anaesthetic employed was the essential factor, and the following table shows the incidence of these complications after various types of operation.

TABLE I

Operation	No.	Fever and Cough	Cough	Total	%
Amputation digit	31	0	0	0	0
Amputation limb	10	0	0	0	0
Appendicectomy	98	26	9	35	36
Circumcision	41	0	0	0	0
Cystoscopy	38	0	0	0	0
Débridement	149	1	2	3	2
Haemorrhoidectomy, etc. ..	58	0	0	0	0
Hernial repair	192	61	26	87	45
Laparotomy	17	4	2	6	35
Meniscectomy	57	0	2	2	4
Miscellaneous	194	3	1	4	2
Nephrectomy, etc.	3	1	0	1	33
Orchidectomy, etc.	51	2	2	4	8
Orthopaedic operations ..	114	0	0	0	0
Perforated peptic ulcer .	6	2	1	3	50
Plaster	123	0	0	0	0
Tonsillectomy	113	1	0	1	1
Trendelenburg operation ..	128	0	1	1	1
Minor operations of less than 10 minutes' duration ..	577	0	0	0	0
Total	2,000	101	46	147	7·3

It is interesting to compare the figures for hernia repairs (average duration of anaesthesia, 27.34 minutes) with those for Trendelenburg operations (average duration of anaesthesia, 27.55 minutes). The types and amounts of anaesthetic employed were entirely comparable.

It may be argued that the extra depth of anaesthesia required to obtain the necessary relaxation for abdominal operations is a factor in the causation of respiratory complications. Against this the figures for haemorrhoidectomies should be noted. Twenty-three of the cases quoted were performed under lower-second-plane inhalation anaesthesia; the remainder were done under low spinals.

Intubation.—Out of 192 cases in which endotracheal tubes were passed 12 (6%) developed complications; 9 of them were abdominal operations. This percentage corresponds very closely with that obtained by Campbell and Gordon (1942) in a series of Canadian soldiers.

Complications after Hernia Operations

Incidence with Various Anaesthetics.—As hernia repairs are the largest group with a high "chest" incidence an analysis has been made below of the types of anaesthetic used.

Table II.—*Service Cases*

Anaesthetic	No.	Fever and Cough	Cough	Total	%
Pent.–N_2O–O–ether (plus) ..	29	13	4	17	59
Pent.–N_2O–O–ether (minus)	20	3	2	5	25
Pent.–N_2O–O–vinesthene ..	15	3	1	4	27
Pent.–N_2O–O–trilene ..	44	11	7	18	41
Pent.–N_2O–O	10	3	1	4	40
Continuous pentothal ..	2	1	1	2	100
Cyclopropane	8	3	2	5	62
Spinal	4	2	1	3	75
N_2O–O–ether (plus)	15	8	1	9	60
N_2O–O–vinesthene	7	2	1	3	43
N_2O–O–ethyl chloride ..	1	0	1	1	100
N_2O–O–trilene	13	4	2	6	46
N_2O–O–trilene–ether (plus)	3	1	1	2	67
Closed circuit ether	7	3	0	3	43
Oxford vaporizer–ether ..	10	2	1	3	30
Oxford vaporizer–trilene ..	4	2	0	2	50
Total	192	61	26	87	45

Ether (plus): More than one ounce of ether per half-hour of anaesthesia.
Ether (minus): Less than one ounce of ether per half-hour of anaesthesia.

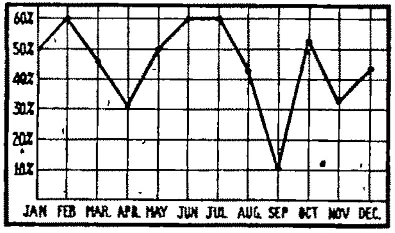
These figures are admittedly much too small to show the real complication incidence of any of the types of anaesthetic, but they do tend to show that there is little real difference between them.

The incidence among hernia repairs on civilians during the same period was as follows.

Table III.—*Civilian Cases*

	No.	Fever and Cough	Cough	Total	%
Men	36	5	3	8	22
Women ..	18	2	1	3	17
Children ..	8	0	0	0	0
Total ..	62	7	4	11	18

Season.—The seasonal incidence of complications following hernia operations showed a peak of 60% in February, falling to 31% in April, rising to a fresh peak in June of 60% and then falling to 11% in September.



Graph showing seasonal incidence of complications after hernia operations.

Bacteriology.—No predominating organism was found in a small series that had their sputa examined. When more than one case from the same operating list developed coughs their sputa showed no evidence of a common infection.

Age.—An analysis of the various age groups showed nothing of interest: 18 to 25, incidence 39%; 25 to 30, incidence 54%; 30 to 35, incidence 46%; 35 to 40, incidence 55%.

Radiological

A small series of cases, mostly hernia repairs, were examined with *x* rays on the day after operation to observe movements of the diaphragm. They were examined lying, with the tube overhead centred over the diaphragm and the screen held below the bed. The movements could usually be seen clearly, but in some cases it was difficult to make out the movements on the left side owing to the heart shadow. It was found that there was a considerable variation in different patients. In some, very little movement of any sort could be detected with normal breathing; in others the movements were quite normal, and comparable to non-operated controls. In a small series of orthopaedic cases the movements were normal. In the majority of cases the movements were symmetrical, but in a few instances one side showed a slightly diminished excursion compared with the other, and this was not necessarily on the operated side. In two cases the right dome and in one the left dome of the diaphragm was raised but showed movements.

In re-examined cases in which there was diminished movement it was found in all instances to have returned to normal on the fourth day after operation. Table IV shows the results.

Table IV

Operation	Movements of Diaphragm		Chest Complications
	Right	Left	
Left ing. hernia	—	— —	None
Left ing. hernia	×	×	None
Right ing. hernia	—	—	Cough, no fever
Bilat. ing. hernia	×	×	Cough and fever
Left ing hernia .. .	×	×	Cough, no fever
Right ing. hernia	—	×	,, ,,
Appendicectomy	— —	—	Cough and fever
Right ing. hernia	× ×	× ×	None
Left ing. hernia	×	×	,,
Right ing. hernia	× ×	× ×	,,
Right ing. hernia	×	×	,,
Left. ing hernia	× ×	×	,,
Right ing hernia	—	—	Cough, no fever
Left ing. hernia	×	—	,, ,,
Right ing. hernia	—	—	,, ,,
Left ing. hernia	— —	— —	Cough and fever
Bilat. ing hernia	× ×	× ×	None

Movements are classified arbitrarily as:
× × Full normal movement; 3/4 in. to 1 in. excursion with deep breathing.
× Decreased movement fair excursion, about 1/2 in. with deep breathing.
— Little movement; some increase with deep breathing.
— — Hardly perceptible movement; not much increased with deep breathing.

The series is admittedly too small, but of the nine cases which developed coughs seven showed definitely diminished movements of the diaphragm, while no coughs developed in four cases which were noted as having full normal excursion. Support is given to the view that diminished ventilation of the lungs is a factor of some importance in the development of chest complications.

Summary and Conclusions

The site of operation is the most important factor. Any operation involving the abdominal wall is more likely to be followed by a cough than one in any other part of the body.

The type of anaesthetic used has little bearing on the incidence of these complications.

Intubation, *per se*, is not a factor.

The incidence is higher in Service cases than in civilians.

There is an increased seasonal incidence in February, June, and July.

Diminished ventilation of the lung is a factor of importance. This is probably the result of pain on breathing. When the pain is past and the patient is able to ventilate his lung freely the complications subside rapidly.

The more serious chest complications can be minimized by starting active movements as early as possible.

We wish to express our thanks to the Regional Hospital Officer for permission to publish this report.

A certificate of disablement under the Workmen's Compensation Act may now be given by the Examining Surgeon for the district in which the workman lives or to which he has been removed for treatment. Hitherto this certificate could only be obtained from the Examining Surgeon for the district in which the man worked.

CAUSTIC SODA BURNS: THEIR PREVENTION AND TREATMENT

BY

H. TERRY, M.B., Ch.B.

I.C.I. (Alkali) Ltd.

Caustic soda, widely employed before the war in various manufacturing processes, is finding increased use in many wartime industries. There is a demand for information on the best way to prevent or deal with the injuries that may result to the workers, and this article is an attempt to satisfy that demand. It is based on thirteen years' experience in a works where many tons of caustic soda are manufactured every day. It is also hoped that criticisms and fresh ideas may be forthcoming for the improvement of the methods here described.

These methods have been evolved gradually. Before they were adopted a large number of men were always away from work with caustic soda burns of the skin, which took many weeks or months to heal. These burns had the appearance of black leather inlays in the skin. There are lifelike wax models of such burns in the Home Office Museum, Horseferry Road, Westminster.

Previously, caustic soda burns were treated by the application of bicarbonate of soda—with the intention that it should react with the caustic soda to form carbonate of soda—followed by washing with plain water. The results of this old-established treatment were unsatisfactory. For several days the burns appeared to become deeper each day. The sloughs were allowed to separate spontaneously, and the resulting exposed area of granulations showed no sign of healing for a considerable period and afterwards healed very slowly. On one occasion, to obtain rapid healing, a narrow burn on the forearm was excised with a margin of healthy skin on each side and the wound was sutured. Microscopical sections of the excised burn were prepared. The burn appeared to be a structureless coagulum, the adjacent tissue being crowded with leucocytes. The phenomena observed in inadequately treated caustic soda burns suggested that the coagulum of necrosed tissue held some uncombined caustic soda, which diffused into the deeper tissues for a few days, increasing the depth of the destroyed tissue and perhaps impairing the vitality of adjacent tissue that was not actually necrosed.

Caustic soda burns of the eye formerly were washed out with boric acid solution for two to five minutes at the time they happened. A prolonged period of inflammatory reaction followed, with the formation of granulation tissue over the sclerotic and the inner surfaces of the eyelids. This resulted in symblepharon. Some of the old hands have tough bands of adhesion between the eyelids and the eyeball, limiting the movements of the eye and causing considerable inconvenience. Burns of the cornea were still more serious.

Prevention

The engineer conducting a process involving the use of caustic soda should make it, when possible, a closed process, so that workers cannot come in contact with the substance. If this is impossible, pools of liquid caustic soda on the ground or leaking pipes, tanks, etc., should not be allowed. If, in spite of all precautions by the works management, the worker comes in contact with the caustic soda, the part of the body affected should at once be drenched with a current of neutralizing solution, not by immersion or compresses.

At first sight a weak solution of an acid such as citric acid, acetic acid, or hydrochloric acid appears to be a satisfactory neutralizing medium; but weak acids, if used as irrigants, might react with the tissues as well as with the caustic soda. Ammonium chloride, on the other hand, is a neutral salt that will not react with the tissues but only with the caustic soda with which it makes contact, instantly neutralizing it, with the formation of sodium chloride and the release of ammonia, which is washed away by the bulk of the unchanged irrigating solution. Our adoption of this treatment during the last 12 years has almost brought about the disappearance of caustic soda burns of the skin.

Caustic Soda Burns of the Skin

Throughout the caustic soda plant are placed large vessels (aspirators), each containing 5 gallons of 5% solution of ammonium chloride, in cupboards with open fronts, painted red to attract attention. These vessels are placed also at other points in the works where caustic soda is used. The necks of the vessels by which the solution is introduced are closed by a large rubber stopper. The rubber stopper is penetrated by a thistle-tube, to admit air for the easy withdrawal of the solution. The bulb of the thistle-tube is lightly packed with cotton-wool to prevent caustic soda dust from falling into the solution and destroying its usefulness. There is a rubber bung at the base of the aspirator, penetrated by a large glass tube to which a rubber tube about 6 feet long is attached. A spring clip controls the rubber tube and serves to hang up the latter on a hook when not in use. The clip can be instantly slipped off the tube when necessary, thus releasing a free flow of the solution. If a man gets caustic soda, solid or liquid, on his skin or clothing he runs to the nearest aspirator, unhooks the tube, presses the clip, and releases a deluge of the solution on the part affected. This stops the action of the caustic soda instantly, and in the great majority of cases prevents a burn. The number of caustic soda burns has been very greatly reduced by this method. It has gained the confidence of the men, who appreciate what it does for them. As an indication of this, as much as 12 to 20 gallons may be used on the plant in 24 hours without any caustic burn taking place. It is an advantage that the ammonium chloride solution is perfectly harmless to the tissues and will not injure the eyes (it has a very corrosive action on most metals).

If there has been such delay in the application of the ammonium chloride that destruction of the epidermis has taken place, and there is in fact a burn, the part should be drenched with a current of ammonium chloride solution for 10 to 15 minutes and then with plain water or normal saline for one hour continuously. This treatment will minimize the severity of a burn and prevent it becoming as deep as it otherwise would. It is then treated as a heat burn. Everyone has his own ideas about the treatment of burns; but we have treated them by washing the area with soap and water, removing dead tissue by a gauze swab soaked in alcohol, and then washing with ether. A fourfold pad of plain white sterilized lint soaked in a 2% solution of tannic acid is then applied and secured by a bandage. This pad is left in place, without attempting to separate it, until it is able to fall away by its own weight when the bandage is removed. This takes place in three weeks, more or less.

In the uncommon cases in which a burn has occurred through delay in irrigating with ammonium chloride solution, this has happened because access to the ammonium chloride solution has not been obtained soon enough (30 to 40 seconds), and occasionally a man has been unaware of contact with caustic soda until burning has taken place. In rare cases a man of dull wits has not troubled to go to the solution and has had to be treated for a deep burn of the old type. Deep caustic soda burns of the skin when they occur have lately been treated by obtaining a firm crust by the application of the tannic acid compress and, after this has formed, applying blue paint to the burn and dressing it with gauze soaked in blue paint. Blue paint was introduced by Bonney, and consists of 1 part brilliant green, 1 part crystal violet, 99 parts rectified spirit, and 99 parts water. This lessens the risk of infection in a deep burn.

Caustic Soda Burns of the Eye

The wearing of properly designed and well-fitting goggles should be compulsory, and this will usually prevent caustic soda from reaching the eye; but it seems impossible to ensure that goggles shall be properly worn on every occasion when there is danger. For the treatment of these cases, eyewash-bottles should be available every few yards in any plant where there is possibility that caustic soda in solid or liquid form may reach the eye, and should be placed in little cupboards fixed at a convenient height, with open fronts and painted red to be conspicuous. The bottles, which contain 5% ammonium chloride solution, should be 8-oz. wide-necked ones, the neck closed with a rubber stopper with two holes—one for the air-inlet tube, which is carried to the bottom of the bottle and need only project from the stopper half an inch, and the other for the irrigation tube, which is bent at an obtuse angle outside and penetrates only for about a quarter of an inch beyond the stopper inside the bottle. The eyewash-bottle is used by turning it upside down and flushing the eye by gravity flow. Any attempt to modify the bottle so that it may be used like a wash-bottle in a chemical laboratory, by mouth-blowing, must be forbidden. It may be injurious.

If a man gets caustic soda in the eye, first aid must be given without delay: for this reason every man should be provided with a whistle to summon aid if necessary. Delay may lose an eye. The first-aider must take a wash-bottle from the nearest cupboard and, parting the eyelids with the finger, flush the eye with the contents of the bottle. The patient should then be taken at once to the plant surgery, which should be close to the caustic-soda plant and preferably with a laboratory adjacent, as this will ensure that a man trained in ambulance work is always available. About four specially trained men must be available on every shift, to give treatment in the plant surgery. Two of them must have instructions to leave their job and attend to the injured man immediately. He should be placed flat on his back on a couch, the foot of which is raised slightly. The eye must be irrigated continuously for one hour by the clock, with which the plant surgery must be provided. Irrigation must be performed for the first five minutes with 5% ammonium chloride solution, and for the rest of the hour with boric-saline solution, prepared as described below. During the irrigation care must be taken to pull the lower eyelid down gently so that the irrigation may reach the inferior fornix; and the injured man should be told to roll his eye from side to side so that the conjunctiva of the inner and outer corners of the eye may be reached. The upper eyelid should be gently elevated by the fingers of the first-aider, and the patient told to turn the eyeball downwards periodically so that the conjunctiva of the upper fornix may be reached.

This irrigation of one hour's duration is of supreme importance, and must be started at once. To send a case to hospital without such preliminary irrigation confronts the hospital with damage which is irreparable and which could have been prevented at the time of the accident by the measure described. In practice this treatment has reduced the time of recovery of caustic soda burns of the eye from weeks to days.

If the case is to be attended to by the works doctor he will see the patient every day and will instruct the ambulance-room attendant to irrigate the eye with warm boric-saline for 5 or 10 minutes three or four times a day, afterwards passing a blunt-pointed glass rod loaded with soft boric ointment first of all between the upper eyelid and the eyeball and then between the lower lid and the eyeball. If this is done no case of symblepharon will ever occur. The doctor will use atropine drops, argyrol solution (20%), or hot fomentations where he considers these measures are indicated. We find it advisable to adopt the first two measures in all but the mildest cases. It will be necessary for one man to be responsible for the ammonium chloride irrigators and eyewash-bottles. He must inspect them every day and fill all those that have been used. The works doctor will occasionally examine these vessels to ascertain that this is being done. Pools of caustic soda liquid on the ground and leaking joints will of course not be tolerated by the engineer-in-charge. If they are, the works doctor should have something to say about it.

With us, the tannic acid solution is made up in winchesters of 2.5-litre capacity; the date is written on the label, and any that has not been used is replaced by fresh solution at the end of three months. It is a great advantage, too, that it should be ready for instant use: tablets dissolve slowly. The cost of renewal is negligible. The quantities used are:

Tannic acid	50.0 grammes
Mercuric chloride	1.25 „
Water	2.5 litres

The boric solution is kept in winchesters at double strength in order that it may be diluted with an equal quantity of warm water when it is to be used. One ounce of common salt and half an ounce of boric acid are dissolved in a winchester of distilled water. We have found it convenient to have this solution ready made up in winchesters for immediate use. Saline by itself grows a mould. The addition of the boric acid prevents this happening.

Summary

Cases of contact of caustic soda with the skin are dealt with by immediate irrigation with 5% solution of ammonium chloride; by which means a burn is prevented if the irrigation is done within 30 to 40 seconds of contact.

If delay has resulted in a burn; its severity is very greatly lessened by irrigation with ammonium chloride solution.

Irrigation of the eye with 5% ammonium chloride solution, followed by irrigation with warm boric-saline lotion for one hour, reduces the severity of the eye injury to a very marked degree, so that recovery takes place in one-fifth to one-seventh the time taken with older methods.

Treatment by ammonium chloride solution must always be carried out by irrigation, never by immersion in a static solution or by compresses.

Medical Memoranda

Notes on Treatment of Respirator Dermatitis

Since the publication of Petro's article on respirator dermatitis (*British Medical Journal*, 1942, **1**, 631) 25 cases have been admitted to a certain military hospital. The first 13 cases were treated on lines similar to those laid down in that article—viz., using calamine lotion and liniment, Burow's solution, and various creams such as 1% ichthyol in zinc cream. In no case could the progress be described as satisfactory, and in order to reduce the number of days of hospital treatment other methods were adopted.

The most successful method was what I shall call the saline soak technique. In this series 12 cases were treated; every case was a severe affection, associated with vesiculation, weeping, and crusting. With few exceptions they responded dramatically to the use of normal saline soaks, similar to those for the treatment of burns. Very rapidly the crusts are removed, the weeping ceases, and epithelization occurs without delay.

DETAILS OF TECHNIQUE

A white lint mask covering all affected areas is soaked in normal saline and applied to the face areas and covered by jaconet. It is essential to keep the lint moist throughout; this can be done by pouring on normal saline at frequent intervals. If the lint should become dry it is vital to soak thoroughly before removing. It is advisable to remove the lint from the face four-hourly, and to renew, so as to remove crusts. In some cases the face returned to its normal condition in 24 hours, and in all cases there was a rapid improvement. When the weeping areas have epithelized either zinc cream or 1% ichthyol paste should be applied.

A typical example is illustrated in Pte. A., aged 18, who was admitted to hospital on Dec. 4, 1942, two weeks after he was called up, having worn his respirator for 10 minutes the week previously, and again for 30 minutes three days before admission. The rash appeared 24 hours before he was admitted. He was suffering from a typical respirator dermatitis, affecting the forehead, cheeks, chin, and tip of the nose, all areas being covered with golden crusts. This case was treated with normal saline soaks in the manner described; after 24 hours there was a marked improvement, all crusts having disappeared, leaving a clean raw area. Treatment was stopped after 48 hours and the condition was cured in three days. Not all cases clear so dramatically, and most require a little zinc cream following the saline.

COMMENT

All these cases were moderately severe, affecting the contact areas of the face—viz., frontal, malar, masseteric, mental, and submental areas, with occasional lesions on the nose. Some cases proved more resistant to treatment than that of Pte. A., but comparison with other methods shows a marked advance. Another point of importance in the treatment is the advisability of not performing any patch test with rubber from the face-piece of the patient's own respirator until the skin is settling down or even healed, as a number of cases were aggravated by so doing; and even in one case after the skin was thoroughly healed the patch test caused relapse.

The saline technique seems to be the method of choice, and certainly takes precedence over those mentioned in the article quoted.

E. COLIN JONES, M.B., B.S.,
Lieut., R.A.M.C.; Graded Dermatologist.

Reviews

DIGESTIVE COMPLAINTS

Digestive Diseases in General Practice. By John H Willard, M D., F A C P. Foreword by George Morris Piersol, M D, F A C P (Pp. 449; illustrated $5 50.) Philadelphia. F A. Davis Company 1942.

The state of the stomach is so largely a mirror of the state of the body and mind as a whole that Dr. Willard does well in this book to insist at the outset that when dealing with patients with digestive complaints it is essential to give adequate time to listen to "the often boringly detailed account" of symptoms, for by letting the patient talk the medical man will often learn much of his whole make-up. This should be followed by specific questions usually needed to clarify the position; the physical examination then takes place under appropriate conditions. All these steps are explained in simple, lucid language without undue insistence on minutiae, and the relevance of the various laboratory techniques is briefly considered. After this general introduction the various digestive diseases are regionally described, with excellent *x*-ray illustrations. Throughout, emphasis is laid on the simulation of organic disease by functional states, and on the aggravation of the former by the latter. The views as to the relation between gastric carcinoma on the one hand and peptic ulcer or gastritis on the other are judicially considered without dogmatism. Indeed, a distinguishing feature of the whole work is avoidance of the two pitfalls of undue dogmatism and inconclusive vagueness. Comparatively recent work such as Crohn's on regional ileitis receives adequate notice, but in general it is the ordinary things met with in everyday practice to which attention is chiefly devoted.

Three things are omitted that we should have liked to see mentioned: the use of the mercury tube for achalasia of the cardia rather than an expanding dilator; Murphy's sign for gall-bladder trouble; and the administration of insulin as well as dextrose in order to increase the glycogen content of the liver in cirrhosis. But these may be matters of opinion. An appendix of laboratory methods and diet tables concludes a really useful and practical book.

FORENSIC BLOOD GROUPING

Medico-Legal Blood Group Determination: Theory, Technique, and Practice. By David Harley, M D, B Sc, F.I C (Pp 119; illustrated. 12s. 6d.) London: William Heinemann Medical Books. 1943.

Although medico-legal blood grouping has not been developed in this country, especially on the paternity side, to anything like its extent in other countries, yet we have produced the first monograph in English on the subject. Dr. David Harley, as he gracefully acknowledges in his dedication, is a pupil of the late Dr. Francis Martley, whose work in serology at St. Mary's Hospital made its department of chemical pathology known and respected throughout the scientific world. This book gives some idea of what the solid, patient work of Dr. Roche Lynch and its author have accomplished in the last twenty years. They have assisted the police in very many cases in which the grouping of blood stains, cigarette stubs, and the like could narrow the field of suspects. Owing to legal handicaps, they have not had the wide experience in disputed paternity cases that a similar department would have had in a Continental country. Nevertheless, Dr. Harley is able to analyse 65 cases of this class in which his department assisted; and what he does not recount is the indispensable part that it has played in evolving a technique which makes the evidence of its exponents unshakable in court, and thus in demonstrating practically to lawyers and legislators the value of blood-grouping evidence in paternity cases. Dr. Harley reprints the Bastardy (Blood Tests) Bill which Lord Merthyr introduced in the House of Lords in 1939, together with the highly favourable report made upon it by the Select Committee.

This volume contains in compact and economical form everything of value in the history, genetics, and serology of forensic blood grouping, and should be of the greatest use to all workers in this field. The sections on the ABO and the MN group systems and their heredity, and the theory of their judicial application, cover familiar ground, but do so with an ordered economy of language which makes reference easy. The technique of collection, testing, and interpretation which Dr. Harley describes has been thoroughly tested by daily use. The great interest of the book lies in its record of actual case-work, which shows strikingly the difficulties and disappointments of this class of investigation: in case after case the results are unhelpful, either through the insufficiency or contamination of the stains which had to be tested, or because the groups of the accused and the victim were the same. Now and again, however, the tests come into their own. A woman was found in a cellar dead from head injuries and strangulation. Blood stains were found on the watchman's jacket and cap, and he was suspected of the crime, but tests showed that these stains could not have come from the deceased woman, and so they did not connect him with the murder. In earlier days they might have been sufficient to hang him. Dr. Harley observes that the defence do not always seem to realize that the tests may exclude but can never identify, and so are far more the concern of the defence than of the prosecution. Their use will increase as lawyers come to know them better; and towards the spreading of this knowledge Dr. Harley's book will contribute greatly.

MAXILLO-FACIAL INJURIES

The Dental Treatment of Maxillo-Facial Injuries. By W Kelsey Fry, M R C S, L.D S, P. Rae Shepherd, Alan C. McLeod, and Gilbert J Parfitt With foreword by Prof F R. Fraser, M.D, F R C.P. (Pp 250; illustrated 16s.) Oxford. Blackwell Scientific Publications, Ltd. 1942.

The authors of this book have had the opportunity of more extensive experience in the treatment of maxillo-facial injuries during the present war than the average dental surgeon of a civilian hospital receives in a life-time. This book, based on their own experience at the East Grinstead unit, describes in detail the methods of treatment which were devised during the last war and which have now been brought up to date in the light of that experience. The work is based on sound common sense and an intimate knowledge of general surgical principles. It is clearly and concisely written and the illustrations and diagrams are really excellent.

The reader may at first feel that the methods of treatment advocated are unnecessarily complicated, but war injuries of the face, with fractures often comminuted and with considerable loss of tissue, are so different from those of civilian practice that great ingenuity is essential to overcome the difficulties of treatment. Much that they describe could be done only at a specialized hospital, but the authors rightly insist that dental surgeons in the Forces must be cognizant with the methods they employ. One of the best chapters in the book, however, is devoted to field and preliminary hospital treatment and the more simple ways of treatment which are often satisfactory.

This book, which is a real contribution to a very specialized branch of war surgery, shows the good team work of the dental surgeons attached to the various maxillo-facial units.

SCHOOL HEALTH IN NEW YORK CITY

Solving School Health Problems The Astoria Demonstration Study. Sponsored by the Department of Health and the Board of Education of New York City By Dorothy B. Nyswander, Ph D. (Pp 377 $2 00 or 11s 6d) New York: The Commonwealth Fund; London: Oxford University Press. 1942

In the light of previous investigations conducted since 1923 an intensive experimental Study of the School Health Service in New York City was launched in 1936 and completed in 1940. A report on the findings of the study by its Director now appears as a publication by the Commonwealth Fund.

The principal scene for the work of the study was the Astoria Health District, which was taken as representative of the city as a whole. Of the eighteen public elementary schools in this area, eight, with a total attendance of 8,000 children, formed the experimental field. Five of the eight schools had children from poor families. When the study began each child was due to receive two routine medical inspections in the course of its school career—the first on entering school and the second before leaving. The study staff made the experiment of abolishing the second routine inspection and concentrating, in its stead, upon the inspection of children of all ages selected as "cases" by their teachers and school nurses jointly. As a result of this change 67% of all children on school registers were brought under medical or nursing care. The conclusion was drawn that "the right children" were thus getting the attention they needed, and the method apparently is now in force in all New York schools.

The inspecting school doctors are on a part-time basis, most being in general practice. Other doctors in private practice provide treatment for referred cases at the parents' expense and, when requested, report to the school authority on the child's condition. Private practitioners may also submit reports on children due to begin school life.

Among the titles of other articles in this interesting report are "Teacher Participation," "Tasks of the School Nurse," "Medical Records," "Visual Acuity," "Loss of Hearing," and "The Care of the Cardiac Child."

Notes on Books

A third edition has now appeared of Miss MINNIE RANDALL'S book *Training for Childbirth from the Mother's Point of View* (J. and A. Churchill; 10s. 6d.). The author is the principal of the school of massage and sister-in-charge of the department of physiotherapy at St. Thomas's Hospital, and the post-natal exercises so well described and illustrated owe their beginning to Dr. J. S. Fairbairn, with whom she worked when he was in charge of the obstetrical and gynaecological departments. On his retirement Dr. Fairbairn urged her to widen the scope of this work to include pre-natal instruction. The aim and design of the exercises have been much extended since that time, and the pre-natal section is now based largely on Dr. Kathleen Vaughan's *Safe Childbirth*, and the exercises conform to the principles laid down by Dr. Vaughan. The section on relaxation is based on the teaching of the Archer Nerve Training Colony at King's Langley. Miss Randall makes full acknowledgment to these and others who have helped in preparing and rearranging the contents of this most useful and admirably illustrated book.

Vitamins and Minerals for Everyone, by ALIDA FRANCES PATTEE (G. P. Putnam's Sons; 10s.), is so simply written that almost any boy or girl of 14 years of age could understand it. Each vitamin and mineral requirement is treated separately and the best-known facts about it are stated in answer to questions—e.g., What does vitamin A do for us? What is vitamin A? How much vitamin A do we need? etc. The use of each vitamin is illustrated by a little story, always with a very happy ending. Useful tables of food values are given, and sample menus which would provide the daily requirements as set forth by the Committee on Food and Nutrition of the National Research Council, May, 1941. The information given is sound, and where evidence of the human being's need is not adequate—e.g., for vitamin E—that is clearly stated. The book is well printed and bound, and the reproductions of photographs of animals given and not given adequate supplies of each vitamin are very good indeed.

First Aid in the Royal Navy (H.M. Stationery Office; 2s.), in addition to covering the usual ambit of first-aid manuals, contains articles on the treatment of poisoning by the agents used in chemical warfare, of such conditions as immersion foot, phosphorus burns, and blast injuries, and on the movement and stowage of casualties. It is convenient in size and well printed and illustrated, and altogether an excellent production. Our chief criticism is that it lacks an index, which, in a first-aid book as full as this, is important as a guide to the appropriate chapter and verse required in an emergency. Efforts towards simplification have perhaps been a little overdone in some directions—e.g., to call the fibula the brooch bone seems rather to be straining at a gnat, while the definition of shock on page 4 reads strangely. Our sympathy is with the author, nevertheless, in the attempt to provide a simple definition of shock, and for the little book as a whole we have nothing but praise.

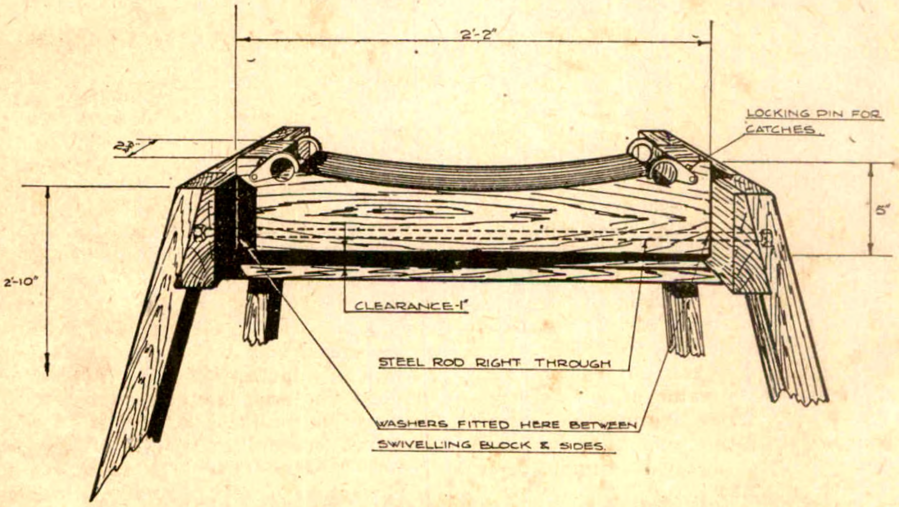
The *Dentists Register* for 1943 has now been published for the Dental Board of the United Kingdom by Constable and Co., price 15s., post free. The total number of names appearing on January 1 of this year is 15,192, being 96 more than the figure for 1942. All the new entries added were of persons registered as graduates or licentiates.

Preparations and Appliances

RESUSCITATION BY ROCKING

Dr. N. HOWARD MUMMERY, ex-chairman, Association of Industrial Medical Officers, writes:

Recent articles in the *Journal* remind us of the debt we owe to Dr. F. C. Eve, who is still actively engaged in investigating the physiological and mechanical problems his method of resuscitation involves. Being familiar with his original and rather cumbersome apparatus, and desirous of using the method for resuscitation at an aircraft factory where test pilots and cadets of an attached flying school are liable to come down in water, I designed a simple modification of the original some six months ago. Dr. Eve himself has tried and approved this and has urged me to publish the details in the hope that rocking resuscitation may become more generally available. Rocking, as Dr. Eve suggests, should be started at once in the rescue boat across the arms of two men facing each other with clasped hands and preferably with a third person grasping the patient's extended legs, and be continued by the Schäfer method during rapid transport to the ambulance centre, where he is placed on the rocking apparatus. While this is being used, at a speed not exceeding 10 cycles per minute with a four-second pause at the end of each stroke, the patient is stripped, rubbed down, blanketed, and other restoratives are applied.



Description of Apparatus

The apparatus consists of a wooden block 2 ft. 2 in. long, 5 in. high, and 2¼ in. thick, which is free to turn on a steel rod, transfixing both its base and the extended side pieces of a broad-based trestle 34 in. high. The upper surface of the block is hollowed to receive the sag of the loaded stretcher, and a semicircular depression near each end receives the poles of the standard A.R.P. steel stretcher. The poles are held in place by metal claws, two on each side, which turn on a short axle passing through the wood block and held in position by locking pins. The metal bands holding the steel mesh of the stretcher to its poles prevent any longitudinal movement of the loaded stretcher. The patient's wrists and ankles are tied to the stretcher handles by clove-hitch bandages.

THE SUPPLY OF WATER TO RABBITS AND GUINEA-PIGS

BY

E. L. KENNAWAY, M.D., F.R.S.

The Chester Beatty Research Institute, Royal Cancer Hospital (Free), London

The welfare of rabbits and guinea-pigs is an important matter in many pathological laboratories and research institutes.

There is a popular idea that rabbits and guinea-pigs "don't drink"; this is not true, as anyone can demonstrate by offering water to rabbits which have not had an adequate quantity of it in any form. Rabbits in captivity, when supplied with an abundance of fresh green food, may not drink water offered to them as such. Whatever the origin of the idea, it has given rise to a most unfortunate convention that rabbits and guinea-pigs can live on a very dry diet of hay and bran at times when shortage of greenstuff allows only a few leaves for each animal daily; if this is the only source of water the animals must suffer severely from thirst and will drink greedily from a bowl of water. Rabbits may show even less resistance than dogs to experimental anhydraemia (Marriott, 1923).

One is often told that the supply of water in bowls to rabbits and guinea-pigs leads to outbreaks of diarrhoea caused by fouling of the water. This danger may or may not be a real one; in any case the alleged danger does not alter the essential importance of a supply of water, and the remedy is not to deprive the animals of water but to find another way of giving it. A member of our technical staff here, Mr. P. J. Ewers, has taken part with me in some experiments on this matter.

Water can be supplied to rabbits and guinea-pigs in several ways which eliminate contamination. (1) Water, in a bowl of the kind generally used for dogs, which is not easily upset, is placed in each cage when the attendant carries out the daily cleaning and feeding, and is passed on to other cages. This gives, at any rate, a daily opportunity of drinking, and prevents acute shortage of water. (2) Some form of bulb or bottle, such as is used in most laboratories, certainly in most American laboratories, for rats and mice, can be employed if the cages provide a suitable attachment. (3) For poultry and cage-birds various sorts of water-vessel are used in which the risk of fouling of the water is very small—for example, some form of trough hooked to the side of the cage as high up as possible.

To obtain some data on the amount of water required by rabbits we placed two of the animals, weighing 2,650 g. (Rabbit A) and 2,080 g. (Rabbit B), on a quite dry diet of bran and clover hay, and supplied water by placing in the roof of each cage a bulb of water, of the kind holding 160–170 c.cm. which we use for rats.[*] The animals soon learned to drink from the nozzles, and after a few days the larger rabbit, A, would empty the bulb in a day, while the smaller drank rather less. After a week we placed a bowl of water in each cage: Rabbit A was not interested, while Rabbit B drank a little in a leisurely manner. Evidently they were not short of water, and their body weights had not altered. Hence a 2.5-kilo rabbit on a dry diet will take about 160 c.cm. of water, or 65 c.cm. per kilo, a day. This calculation provides approximately 4.5 litres of water for a man weighing 11 st., or 70 kilos; this is about twice the total intake of water in food and drink of an average human adult (Evans, 1941; *Macleod's Physiology*, 1941). This result provides a curious commentary on the doctrine that rabbits "don't drink." Possibly the rabbits which were the subject of this experiment took more water than was absolutely necessary. We find that guinea-pigs also drink freely from the glass bulbs, even when supplied with greenstuff. It is merely a superstition that rabbits and guinea-pigs have some special capacity for doing without water: there seems to be no reason why they should not drink as much clean water as they like.

The supply of greenstuff for animals is scanty at certain seasons, especially in the early spring, and now it is reduced by the increased human consumption and the sale of leaves which were formerly stripped off. A small handful of cabbage leaves, such as might be considered a good allowance for a rabbit, weighs 300 to 350 g. The fresh leaves of various kinds of cabbage contain from 80 to 95% of water. A rabbit which ate 300 g. of cabbage which actually contained 90% of moisture would receive 270 c.cm. of water. This is a liberal supply, and possibly such a rabbit would not drink, in accordance with the conventional doctrine about rabbits. But one must remember that greenstuff by the time it reaches the animals may have undergone considerable desiccation, which is often quite obvious. It seems much better, therefore, not to rely upon the variable water content of a variable supply of greenstuff, but to supply water as such at all times.

Rabbits which receive an ample dry diet and inadequate water probably suffer not only from want of water but from want of food. This is suggested by their poor condition and the scanty contents of the gut found post mortem, and by their behaviour when water is supplied. If one places a bowl of water before such an animal one may see that after a long drink it goes at once to the dry food and eats greedily.

The supply of water to rats and mice is referred to in several books which have appeared recently (Staff of the Jackson Memorial Laboratory, 1941; Griffith and Farris, 1942; Grüneberg, 1943). All three sets of authors take for granted that a constant supply of water is required. However, in some laboratories in this country, at any rate until recently, "moist" food with a variable amount of greenstuff was held to be a sufficient source of water. The dry foods were mixed with water or milk, and appropriate amounts of the mixture were squeezed by hand to a consistency which allowed a portion to be placed in each cage. This system is bad in principle because the supply of water is regulated not by the needs of the animals but by the extent to which the food happens to be squeezed by the attendant. So many ways of giving clean water are now available that the "moist" food system should be considered obsolete.

---

[*] Made by Messrs. Howard Rawson and Co. Ltd., Devon Works, Farm Lane, Fulham, S.W.6. The bulbs are readily filled from a brass tube, with narrow side-tubes (made by Messrs. C. Hearson and Co. Ltd., 68, Willow Walk, Bermondsey, S.E.1), attached to the high-pressure water supply. An abundant growth of green algae in the bulbs is of no consequence.

REHABILITATION CENTRE FOR SCOTTISH MINERS

The rehabilitation centre at Gleneagles Hotel, Perthshire, was recently opened by the Secretary of State for Scotland, Mr. T. Johnston, M.P. A part of the hotel is still used as a hospital, for which purpose it was taken over at the beginning of the war, but accommodation has been found in it also for 200 miners (about 80 of whom are already in residence) recovering from industrial injuries, chiefly fractures. Dr. Macleod, the medical superintendent, is assisted by experts in remedial exercises, massage, and occupational therapy. What was formerly a luxurious sitting-room in the hotel is now a large gymnasium, where physical exercises are undertaken under the guidance of an ex-Army instructor; the most complete devices for physiotherapy have been installed, a swimming-pool and spray baths are in use, the entertainment side is not neglected, and, of course, the men undergoing rehabilitation have access to the beautiful grounds and surrounding country. This fitness centre, as it is called, is the result of a careful study by the Department of Health in conjunction with the Miners' Welfare Commission and the Ministry of Fuel and Power. The average duration of stay is about six weeks. The treatment and the courses are free and the travelling expenses of patients are met by the Miners' Welfare Commission. Mr. Johnston, in opening the centre, said that its prime purpose was to restore the men to their full working capacity as speedily as possible. In no way whatever was the service to be run as a means of relieving insurance companies of compensation claims. The patients are examined carefully both on admission and periodically during their stay, information of their medical history is obtained, and they are graded according to the activity of which they are capable. Their remedial exercises are adapted to their needs, and in the occupational therapy room they are encouraged under skilled supervision to work with their hands in wood, leather, and other crafts.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 19 1943

LABOUR AND STATE MEDICINE

The Labour Party has issued two pamphlets[1] setting out its post-war policy on national health services and on local government. There is little in the former that is likely to prove unfamiliar to readers of this *Journal*, and in outline the proposals for a national health service are similar to those recently put forward by the Ministry of Health and temporarily withdrawn. Any policy of the Labour Party in relation to health services has an obvious significance for the medical profession in view of the important part that will be played by that party in post-war England. Its views are presumably not without political effect at the present moment. As might be supposed, the Labour Party favours the introduction of a whole-time State salaried service, and all the arguments in the document before us are made to favour this conception. Its desiderata for such a service are that it should be planned as a whole, preventive as well as curative, complete, open to all, efficient and up to date, accessible to the public, equitable for the medical profession, and that it should be such as to preserve confidence between doctor and patient.. The medical service, it declares, should be organized so as to enable the medical profession to "pull its weight effectively in all those tasks of democratic government which affect the nation's health."

While tribute is paid to the family doctor and the "great service he has rendered to the nation's health," and while his position as "friend and adviser as well as general physician" is sympathetically recognized, the pamphlet asserts that there is "only one way" by which existing difficulties can be removed—the employment of doctors as whole-time salaried officers in well-equipped health centres, thus providing for teamwork between doctors, better contact between general practitioners and specialists, and fuller access to all the resources of modern medicine. The family doctor is criticized as being "a sickness man rather than a health man," that he is out of touch with preventive medicine, that he cannot by himself provide a comprehensive service. The Labour Party adopts the same criticisms of the limitations of National Health Insurance practice as have been familiar to the B.M.A. for a number of years now. But it adds the criticism that "the panel system . . . does not provide sufficient guarantee for the efficiency of the doctors employed," and that the general public "lacks the knowledge for appraising the quality of his [the doctor's] service, and his efficiency is not in fact subject to any adequate control." It may be well to recall here the intention of the Medical Act of 1858. This Act was passed for the express purpose of regulating the qualifications of practitioners in medicine and surgery, through a General Council of Medical Education and Registration, which was to maintain and publish a *Medical Register* containing the names of those registered in accordance with the Act. The public was thus able to distinguish the qualified from the unqualified, and had the assurance that the training, knowledge, and technical skill of the former were under the supervision of the statutory body known by the short title of General Medical Council. The G.M.C. of course also exercises a disciplinary control over those guilty of professional misconduct. In addition to these safeguards there is the disciplinary machinery of the National Health Insurance Acts. It is common ground that doctors need to keep their professional knowledge up to date, and that one of the gravest disadvantages of present-day general practice is that most practitioners have neither the time nor the opportunity for postgraduate study; the B.M.A., in its latest report,[2] has suggested that when a national scheme of medical service is organized periodical "refresher" courses should be made compulsory. What additional restriction or compulsion the Labour Party wishes to place upon the individual doctor is not clear. The one specific complaint it makes against him is best given in the words of the pamphlet: "If he has a manner which ingratiates him with his clients, he can retain and even increase his practice, even though his technical competence may be very low." The pamphlet then observes that under the present scheme the doctor cannot speak "freely, bluntly, as a healer, or as a guardian of good health." Does the Labour Party seriously wish to maintain that ingratiating qualities will be absent in a whole-time service in which promotion depends largely upon the opinions of those employing the doctor? And is it not one of the commonest criticisms of local government medical services that the doctor employed in them not only does not speak "freely, bluntly, as a healer," but has in very many cases to submit to a censorship before he is allowed to publish anything at all on professional matters in professional journals?

The central authority in the service, as the Labour Party sees it, can be no other than the Ministry of Health, but a Ministry with extended powers covering all health services at present controlled by other Departments. In that respect the plan is more thorough than the tentative one of the Ministry. For local administration the country would be divided into regions, and in its other pamphlet the Labour Party indicates something of the character of those regions and the responsibility of their authorities. They must not be so large that a sense of common interest in their government will be lost, but they must be large enough to admit of development. One question which might be asked is whether Greater London, with an inner but very large county administration, and beyond it a still larger zone of unplanned and unrationalized urbanization, may be made into one homogeneous whole: the point is left in doubt. Each of the regional authorities would appoint a health committee, which would presumably be the body controlling the doctors. Nothing is said in either pamphlet about medical representation on these committees or about the setting up of separate medical committees. It must be inferred that the general practitioner and the consultant will be servants of the area authority in the same way as the medical officer: in other words, a new branch of the local government service will be created. The regional authority will have powers in respect of hospital and health centres, mental treatment, district and school medical services, the venereal diseases scheme, and nursing-home registration and inspection. Area authorities—an area being a division of the region, probably an amalgamation of urban and rural authorities, based where possible on county boroughs—will have powers in respect of midwives, maternity and child welfare, notification of infectious diseases, and vaccination. Most environmental health services will also remain with the area authorities. Within each region there will be a series of divisional hospitals for the treatment of all kinds of cases (except infectious cases and certain forms of mental disease). These will be general hospitals, each with from 600 to 1,200 beds, and staffed by perhaps fifty doctors. Although special hospitals will be eliminated, these divisional hospitals will have specialized units arranged in such a way as to prevent overlapping of services in any region. Linked up with the regionally organized hospital and specialist services will be divisional and local health centres—four or more local health centres in a divisional area, each centre served by a team of from eight to twelve general practitioners. It is well that those who have the interest of the voluntary hospitals at heart should be aware of the Labour Party's "simple method of achieving the goal of a unified hospital system." Voluntary hospitals will be given financial assistance in respect of cases referred to them by local authorities; the latter thereby become entitled to a share of representation and control on the governing board; the end-result of this will be that "before long the voluntary hospitals will come under the control of the local authorities, and the conditions of service of staff in all the hospitals will become standardized." As to the cost of the scheme, the pamphlet argues that it would cost little or no more than the present system.

[2] Memorandum of Evidence by the B.M.A. to the Interdepartmental Committee on Medical Schools, *British Medical Journal*, June 5, 1943, p. 702.

In a very brief glance at the health of the nation the pamphlet rightly stresses the effect upon it of poverty and environment; and the statement of the Minister of Food that the nation in general is better nourished on its war-time diet than in peace is cited as an indictment of pre-war policy: "It means that the good resulting from improved distribution has outweighed the injury resulting from the enforced reduction of the national food supply." While this statement may be true in part, it ignores the possibility that such enforced reduction may in itself be beneficial. The effect of poverty, bad housing, and bad environment generally upon the health of people exposed to these evil influences is widely admitted. The matter is referred to in the Labour Party's pamphlet as the first item under the chapter heading, "Our Existing Medical Service." Are we to understand that there is therefore some connexion between the two, and to believe that a whole-time State medical service is the remedy? Is not the remedy to be found in the re-ordering of society rather than in the re-ordering of the medical profession? That reforms in the organization of medicine are needed, and what general direction these should take, are in the main recognized and agreed upon by medical men themselves. But the assumption that seems so widely prevalent in some lay and some medical circles that the men and women in this country are going to be turned into a healthy race through the instrument of the whole-time State doctor and an all-powerful Ministry of Health is, to say the least of it, facile. The doctors will remain the same men, with perhaps a diminished incentive to work, and their patients will (in some respects of health and sickness) remain the same men and women and children—unless they are guaranteed the basic necessaries of life in terms of food, housing, clothing, and recreation in return for honest work, with the safeguard against interruption of income which is the basis of the Beveridge proposals. It is reasonable, therefore, to suggest to our would-be political masters that the house should be set in order first, and the people in it fed and clothed properly, before calling in the doctor.

INFECTIOUS DISEASES AND SOCIAL CONDITIONS

It has been generally recognized for some years that the health of the community is related to environmental and social conditions. The extent of this relationship, especially in the group of infectious diseases, has been an important problem in public health administration. Farr, using large aggregates, first demonstrated in 1875 that mortality progressively increased with the density of the population per acre. The method used for the compilation of national statistics prevented a more thorough study being made, but during the past thirty years, as more details have become available, this subject has attracted much interest, particularly in relation to the infectious diseases of childhood. The trends of these have altered during the past twenty to thirty years—e.g., the changing age incidence of diphtheria and the decline in the death rate from measles.

An important modification in the presentation of vital statistics was made in 1911, when deaths were no longer allotted to the district in which they occurred but were transferred to the place of usual residence. From that date it became possible to compare the mortality of relatively small areas. Previously this could not be done, because, especially in some London boroughs, the death rate of a district was often seriously overstated by the inclusion of deaths in hospitals and institutions within its boundaries. The more detailed housing statistics, which permitted the construction of an overcrowding index, and the grouping of the various male occupations into five social classes which was introduced in the 1921 census, opened up further lines of investigation. Compulsory notification of certain infectious diseases and the gradual addition to these has brought morbidity as well as mortality within the range of inquiry. The statistics of notifications of infectious diseases are imperfect, because they are tabulated without regard to age and sex. For these details it is necessary to conduct a field investigation or to confine the investigation to areas where the local authorities record sex and age of the notified cases. The data for London have formed the basis of several inquiries, and the latest by G. Payling Wright and H. Payling Wright[1] considers the influence of social conditions upon diphtheria, measles, tuberculosis, and whooping-cough at ages 0–4 during the fifteen years 1924-38. The deaths from these four diseases form a large proportion of the deaths among pre-school children.

These diseases have varying epidemiological characteristics, but in all the principal method of spread is by infected droplets. Measles and whooping-cough are transmitted from child to child. Infection from adults is an important additional factor in the distribution of tuberculosis, and carriers are often responsible for the spread of diphtheria. As is well known, the mean age of infection varies for each of the diseases. The authors found that for diphtheria it was 6.3 years, for measles 4.4, and for whooping-cough 3.6 years. A high correlation was found between the mortality at ages 0–4, for the fifteen years, and the proportion living more than two to a room in 1931: the coefficients were for measles 0.838, whooping-cough 0.729, tuberculosis 0.670, and diphtheria 0.503. The relation between economic conditions as judged by the proportion of lower-paid male occupations was also highly related to mortality; the correlation coefficients were for measles 0.589, whooping-cough 0.452, tuberculosis 0.746, and diphtheria 0.591. The first two diseases are more highly correlated with substandard housing than with the social index, while for the other two the order is reversed. The authors conclude that substandard housing is the most important social factor concerned in the transmission of measles and whooping-cough, and that non-specific factors of resistance affected by poverty have little influence upon the outcome of infection. Not only is the mortality from diphtheria closely associated with overcrowding, but it appears that poverty may lead to a higher death rate in the poorer boroughs by lowering the non-specific resistance to infection. In addition to overcrowding, other conditions associated with poverty influenced the mortality from tuberculosis among young children. It is not yet possible, however, to determine how these operate, though factors such as food, clothing, and heating are concerned in maintaining resistance to tuberculosis. The comparisons which were made with the results obtained by other workers showed, on the whole, good agreement.

TREATMENT OF TUBERCULOUS CAVITIES

The treatment of pulmonary tuberculosis is based on two things: general measures to improve the health and resistance to the disease, and local measures to allow rest, relaxation, or actual compression of the diseased lung. If sound healing is to be achieved cavities must be closed, for their persistence carries with it an 80% chance of death within three years. Until a few years ago direct attack on a cavity was considered a surgical heresy, and those cases in which a cavity was accidentally opened during pneumonolysis were so often fatal that this attitude seemed well founded. The last five years has, however, seen the introduction and application of methods of external cavity drainage which are now sufficiently well tried to allow at any rate a preliminary report.

A substantial Continental and American literature already exists, and Sellors[1] and Maxwell and Kohnstamm[2] have lately recorded their experiences in two excellent articles which should be read by all who wish to know more of the treatment, especially in regard to the many important technical details of management. Although there have been attempts by earlier workers, the name of Monaldi will probably always be associated with the first satisfactory work on the introduction of closed-suction drainage for tuberculous cavities; the world-wide interest in the operation dates from his paper[3] presented in 1938. Two years after this J. V. Cussen described in this *Journal*[4] 3 cases treated by Monaldi's method, observing of it: "That remarkable and rapid improvement may be obtained would appear to be certain." In considering the treatment of a tuberculous cavity it is fundamental to understand the pathology of cavity formation, which up to now has been assumed to be directly due to actual destruction of the lung. Although tissue destruction is responsible for the beginning of a cavity, its growth and persistence are more influenced by mechanical factors—namely, thoracic-wall traction during respiration and inflation by air entrapped distal to an inflamed and partly stenosed bronchus. In other words, a check-valve action is set up, and every inspiration drives air past the valve to distend the small initial cavity of destruction into a large and still larger cavity. The denser tissue in its wall is generally due not to fibrosis, as is often thought, but chiefly to compression of surrounding lung tissue with some inflammation. The standard measures of collapse therapy, such as artificial pneumothorax and thoracoplasty, produce closure of a cavity in a high proportion of cases, but at times they fail or are impracticable. Moreover, the question must arise whether closure of a cavity can be achieved by something less drastic than thoracoplasty. Closed-suction drainage is a method which holds out hope in many difficult cases, chiefly of bilateral disease; but from the results of Sellors and Maxwell it does not seem likely that it will supplant thoracoplasty, though it becomes a valuable adjuvant to the operation by diminishing the size of the cavity and by improving the patient's general condition. Both Sellors and Maxwell conclude that the majority of patients so treated will need a thoracoplasty to obtain permanent healing. The introduction of the special fine catheter is a small operation carrying a virtually negligible risk. Gentle suction-drainage strikingly relieves cough—and this is very important when the cough is exhausting—and, in most cases, the cavity steadily shrinks to a small size or to no more than a tube track. Unfortunately, when the tube is removed the cavity often reappears, presumably by the very process of inflation via a bronchus by which it originally grew. This is not to be wondered at if the primary bronchial check-valve action persists. Thomas and his associates[5] have tried to overcome this difficulty by a most ingenious device—the injection into the cavity of some 10 c.cm. of the patient's own plasma. The object is to obliterate the causal bronchial fistulae, and the results in some of the few cases they report are both interesting and encouraging. Further experiences in this method or of others to produce bronchial closure will be eagerly awaited.

SKIN REACTION TO PHENOBARBITAL

Phenobarbital is one of the most useful hypnotics in general use, and since its introduction to the profession in 1911 has been a stand-by to both the general practitioner and the neurologist. Whereas barbitone (veronal) is a combination of two ethyl radicals with the molecular group which constitutes the residue of urea and is more properly known as diethylbarbituric acid, in phenobarbital one of the ethyl radicals has been displaced by a phenol group; hence the name. In former times phenobarbital was probably even better known under the trade name of luminal. It has been found to be of value in epilepsy, and often has advantages over other barbiturates as an ordinary hypnotic. But it possesses the drawback shared by all the members of this series in its liability to produce toxic rashes in susceptible subjects. Phenobarbital is a powerful narcotic poison and is even more toxic than barbitone, but it is not in the cases of acute poisoning that these toxic rashes occur. Very often they are seen when only a single small dose of the drug has been taken, and they are characterized by urticarial lesions of widespread distribution and by intense pruritus. They are usually recognized without much difficulty, and disappear quickly when the drug is no longer administered. Rarer and more serious are the eruptions which make their appearance only after phenobarbital has been given daily during a period of some weeks, with, at first at all events, no apparent ill effects. But when the skin is involved these cases can be severe and even fatal. The eruptions are characterized by exudation and exfoliation with ulceration of the mucous surfaces. Moss and Long[6] have reported two cases of this type: one in a woman who had taken about three dozen pills amounting in all to 1.53 g. of phenobarbital prescribed for the relief of menopausal symptoms, while the other was a negress who in the course of treatment for secondary syphilis took 30 mg. of phenobarbital four times daily for some forty days on account of insomnia and nervousness—her total dose was 4.8 g. Both these patients showed considerable fever, swollen lips, great redness of the conjunctivae, and copious sticky oral and pharyngeal exudate. The cutaneous eruption was generalized: in many places the lesions were crusted, and some of them haemorrhagic. Pruritus was intense. Both patients were extremely ill and appeared to be in great danger. But soothing applications and administration of large amounts of fluid—a treatment not at all easy to carry out owing to the dysphagia produced by the state of the mouth and pharynx and the copious exudation from the mucous membranes—led to complete recovery. At the end of three months no trace was left of the severe ordeal experienced. It is worth while to notice that in neither case were there any of the symptoms of narcotic poisoning such as commonly occur after single massive doses of the drug. This is the rule in such cases. Patients who have taken a single massive dose show no cutaneous symptoms, while those who suffer from the cumulative effect of a series of doses show no nervous symptoms. Moss and Long draw attention to the strong resemblance between these cases and certain others labelled "atypical erythema exudativum multiforme," of unknown cause. They suggest that phenobarbital (or perhaps some allied barbiturate) may well have been the real cause in many of these. A history of drug ingestion is often difficult to obtain, and it is still more difficult to ascertain the name of the drug used.

THE DETERMINATION OF BLOOD GROUPS

Blood transfusion disasters may be caused by faulty grouping. Owing largely to the apparent simplicity of making the tests the standard of accuracy of blood-grouping results is not as high as it might be. It is most unfortunate that, without any immediately obvious difficulty arising, blood-grouping tests are often left, after a few minutes' instruction by a teacher far from experienced, to a person quite unused to laboratory methods. Accurate grouping is not simple, and if errors are to be avoided certain technical principles must be understood and adhered to. There are three essentials: a sound and well-controlled technique; good and reliable reagents; and, last but not least, an experienced worker. The appearance of an M.R.C. War Memorandum[1] on "The Determination of Blood Groups," describing these principles and essentials, is most welcome. Three methods of grouping which in trained hands have given satisfactory results are described, and their relative merits are discussed. It is recommended that one or other should be used by all workers without the introduction of personal modifications. Of these three it is said that where possible the tube method should be employed; if this is impracticable a tile method in which the red cells are used in weak suspension is advisable; and that a tile method in which undiluted blood is added to grouping serum is not advised unless the worker has very considerable experience of this particular procedure. The importance of directly matching the donor's cells against the recipient's serum is stressed. Sources of grouping errors are analysed, and the properties and storage of testing sera are detailed. It really is worth an effort to store fluid sera frozen solid, and where this cannot be done dried grouping serum is recommended. The most important statement in this 19-page document stands on page 4: "It is certain that if the serum were regularly examined for agglutinins, as well as the cells for agglutinogens, most blood-grouping errors both technical and clerical would be prevented." No worker seriously seeking accuracy can ignore this, for it seems impossible to group any considerable number of people by any technique that examines only the agglutinogen content of the red cells without mistakes arising. A section on the subgroups of A, which most workers find so baffling, should help towards a clearer understanding of this admittedly confused aspect of the blood groups. There is an excellent and most useful note on the recently discovered Rh factor. The memorandum sets out in a comparatively small space a large amount of essential information which anybody who has blood-grouping tests to make should study and digest.

A COUNTY BOROUGH IN THE FRONT LINE

The county borough of West Ham, with a population (pre-war) of 300,000, was the first part of the metropolitan area to feel the fury of large-scale air raids. On a September afternoon in 1940 two of its poorest districts, Canning Town and Silvertown, were attacked by incendiaries, and the glow of the fires so lighted guided the bombers which came later the same night. Casualties were astonishingly few, but hundreds were rendered homeless, and an immense emergency problem was created in a matter of hours. *War Over West Ham*[1] is an investigation of the reactions of such a calamity upon the people, the local government, and the social services, and Miss Idle has done her work with Fabian thoroughness. West Ham, though burdened by early slum development, is a progressive borough. To take its health services alone, it has five municipal and six voluntary maternity and child welfare clinics and four school clinics. Only half the county boroughs in England pay midwives' fees in necessitous cases, but West Ham is one of them. Fewer than half provide artificial sunlight treatment or special schools for mental defectives, but again the number includes West Ham. The organization and experience behind these and other services were of great value when the test of the emergency came. Nevertheless, Miss Idle is critical of the borough council, apparently on the ground that the average age of its members is about 60, an indictment—if it is one—which might be brought against many local and national bodies. In A.R.P., she says, the council moved slowly, did not grasp significant factors, was fearful of being by-passed, was obsessed with municipal prestige. Even when it provided the services it had no notion of advertising their availability. She wants young men and women, not people past their prime, in the administration of such a borough. Some of her criticisms are eloquent with the wisdom which comes after the event, and it seems probable that the council might construct a rather different narrative of what happened. Before the authority is censured it ought in fairness to be remembered that it was the first to have to deal with such a situation, and that even though there were delays and unsatisfactory co-ordination in some respects, many services, including the medical ones, made without difficulty fundamental readjustments to meet the emergency.

Of the large numbers of men who have qualified for the medical profession in Northern Ireland since 1938, three out of every four have volunteered for the medical branches of the fighting Services. Almost all of them enlisted immediately on completing their statutory six months' residence in a hospital. So many members of the medical staffs of the Ulster voluntary hospitals have joined up that it has been possible to carry on the work only by bringing back from retirement former senior members of the staffs.

Reports of Societies

NUTRITIONAL PROBLEMS OF INFANCY

In wartime the "susceptible" classes—expectant mothers and infants—need special nutritional care. The Nutrition Society's recent meetings are therefore of special interest. A symposium on nutrition in pregnancy has already been held, and on May 22 there was a conference on nutrition in infancy. A discussion on milk will take place on July 5.

One of the virtues of these meetings of the Nutrition Society is that they bring home to those who attend them just how little accurate information on nutrition is really available: this was obvious at the recent meeting on nutrition in infancy. Many speakers stressed that the baby has no way of telling us how it feels and what it would like. As Dr. H. E. Magee in the afternoon session put it, the baby's response to all discomfort is to "howl." Dr. HELEN MACKAY quoted the work of Dr. Clara Davis in America, who had let 12 babies choose their own foods. Many of the things they ate and did not eat would have probably horrified either the nutritional expert or, the baby specialist—or both. The consumption of ten eggs at a sitting or the failure to take any milk at all for some months were examples of their selection. But all the babies appeared in a state of optimum nutrition at the end of the experiment.

Some Useful Pointers

Dr. Mackay said that in feeding babies three things had to be borne in mind: (1) the tolerance of babies to food; (2) the importance of gradualness—the education of the child to take many kinds of foods if they were given gradually; (3) the importance of early supplements, as babies kept on a milk diet for one year were often retarded. Comparing the recommendations of the American Committee on Food and Nutrition on the requirements of various nutrients in infancy, Dr. Mackay showed that they were higher than those usually adopted in this country. She believed that the American Committee must in some cases have been thinking of artificially fed babies.

Taking various nutrients one by one she made the following points. In breast-fed babies only 10% of the calories came from protein. Milk was the sole source of the baby's protein, whereas some of the fat and carbohydrate might come from elsewhere. The casein of cow's milk was not as good as the lactalbumin of human milk, but the milk of most animals had a higher protein content than human milk because the young of these animals grew more rapidly than humans. As human milk was relatively low in protein it was, probable that in rapidly growing babies (e.g., prematures) the protein of human milk was insufficient. In some places it was customary to give protein to such babies, but not to any great extent in this country. Dr. Mackay was doubtful of the value of such a procedure.

The infant's requirement for calcium was important, but it was difficult to give minimum requirements because they were variable. For example, in a full-term foetus the long bones had a considerable amount of cancellous tissue, and it had been suggested that a baby could draw on some of this calcium. The difficulty of preventing rickets in some premature babies suggested that this might be a fact, as the premature baby would have such a small amount of cancellous tissue to constitute a calcium reserve.

Vitamin D varied considerably in the diet of infants. Babies which were put out of doors regularly throughout winter rarely developed rickets, for, hard to believe though it was, even winter light in this country had some protective action. Premature babies in particular needed vitamin D very early in their lives. Dr. Mackay recommended a routine dose of vitamin D for all babies, which would protect against rickets under all circumstances. One point of special interest made by the speaker was that the vitamin D of concentrated preparations was relatively poorly utilized. Of the other vitamins, little was known of the requirements of vitamin A or of the B complex. The American Committee on Food and Nutrition had recommended 30 mg. per day of vitamin C, although this was probably more than was needed. The fact that vitamin C appeared to be associated with the metabolism of certain amino-acids, particularly in premature infants, suggested that it would be wise to ensure an adequate supply of it.

Most babies had a low level of haemoglobin (which was cured by iron) at the end of the first year. It seemed desirable, therefore, to provide babies with medicinal iron and foods rich in iron in the latter half of the first twelve months of life.

It was important for an infant to have plenty of water and to ensure that it received sufficient *quantity* of food. The latter was sometimes overlooked, as many of the symptoms of hunger often went unrecognized.

Many speakers contributed to the discussion of this paper, but space cannot be given to their contributions, valuable though they were. We should mention, however, some interesting figures given by Dr. S. K. KON of the National Institute for Research in Dairying on the vitamin content of human milk. His figures were obtained from 1,000 samples: vitamin A, 700–850 I.U. per pint (there is little variation in this figure); vitamin C, 12 mg. per pint in winter, 24 mg. per pint in summer; vitamin B_1, 0.07 mg. per pint; riboflavin, 0.13 mg. per pint—this was low compared with cow's milk, which has six times as much.

Wing Cmdr. R. W. B. ELLIS's discussion of the methods of assessment of underfeeding, rickets, and scurvy was extremely helpful and stimulating to all present. Dr. ALAN MONCRIEFF opened his paper with a few unequivocal comments on the misuse of the term "marasmus." He contended that the best way to cut into the vicious circle malnutrition–infection–malnutrition was primarily to treat the infection. He emphasized the point, also made by other speakers, that the bogy of overdosage with vitamin D really was a bogy. One case of his of vitamin-resistant rickets had been treated with half a million international units of vitamin D daily for 6 weeks with no effect on the rickets or on calcification in other parts of the body. He stressed the fact that preparations of cod-liver oil and malt which rarely contained more than 10% of cod-liver oil could not be regarded as either a preventive or a cure of rickets.

Administrative Aspects

The morning session had been devoted to a consideration of the scientific aspects of infant nutrition; the afternoon session, to a consideration of administrative problems.

Dr. J. C. SPENCE made a plea for the provision of separate departments for maternal and child welfare, because each was such a big subject in itself. In the subsequent discussion this was regarded as being perhaps not desirable, because from the standpoint of nutrition the two were indissolubly linked. Dr. Spence believed that some better way must be found of giving technical advice to mothers. He believed that advertisements for patent foods should be controlled.

Dr. H. E. MAGEE, in a thoughtful paper on the public health aspects of infant nutrition, claimed that we should strive towards the ideal of optimum nutrition. He believed that the national milk and vitamin schemes were one of the most important public health measures which had been taken, and he hoped they would be continued. The war had provided us with a unique opportunity to test out nutritional theories, and they had come through with flying colours. Mr. F. LE GROS CLARK, secretary of the Children's Nutrition Council, supported Dr. Magee's comments on the milk and vitamin schemes, and pointed out that they constituted an important precedent, as for the first time food was being distributed according to biological requirements regardless of income.

One matter stood out through the whole of the conference—agreement on the importance of breast-feeding.

The chair at both morning and afternoon meetings was taken by Prof. L. G. PARSONS, professor of children's diseases, University of Birmingham.

At the annual general meeting which preceded the afternoon session Sir John Orr, Dr. L. J. Harris, and Mr. A. L. Bacharach were re-elected chairman, hon. secretary, and hon. treasurer respectively of the society, and Dr. S. K. Kon was elected hon. editor of the Proceedings of the society. In the election for membership of the committee there were five candidates, and Mr. F. Le Gros Clark, Prof. S. J. Cowell, Dr. A. P. Meiklejohn, and Dr. Lucy Wills gained the vacant places.

Correspondence

The Cult of Negative Health

SIR,—In opening the debate in the House of Lords on May 5 Lord Geddes stated that the physical condition of evacuees was better than that of city dwellers in his youth, but that both adults and older children were to a surprising extent lacking in independence and convinced that they were not well. He noted a similar contrast between the conscripts of this war and the young men who served in 1914 and in the Boer War. He further stated that the children, at any rate, had improved greatly through living in the country.

These observations are of great interest, but I think we shall have to look beyond the Government official and the medical profession for the explanation of this cult of negative health. Moreover, since an improvement in physical health appears to have occurred side by side with a deterioration in mental health (which loss of independence and belief in ill-health surely indicate), it would be reasonable to look not to the defences of the body but to the sphere of mental life. I would like to make the suggestion that this belief in ill-health may to a large extent be due to the fact that, in the case of the town dweller, the environment does not *demand* the use of more than a portion of his interests, abilities, and energies.

Biologically speaking, we are animals. Animals could not survive in the struggle for existence unless they learned to satisfy their needs in the most efficient way. In common with animals we have an innate tendency to get what we want with the least possible expenditure of energy. Habit-formation—learning to do things without thinking—is only a part of this economy of effort. The tendency to provide for our requirements by the easiest and quickest means can and does influence a high proportion of all our behaviour. The newly born infant uses practically all its psychic and physical energy in the maintenance of life and in growth. It lives to a very large extent in an inner and sensory world, and is intensely aware of bodily sensations. This condition, though probably unpleasant, is biologically necessary. In physical illness, energy and interest are withdrawn from the outside world. The sick person retreats into himself, and becomes, in this respect, like a baby again. He is acutely conscious of physical sensations and is using all his energies in combating the disease. This turning inwards is again of obvious value. In normal health, however, there is a surplus of psychic and physical energy over and above that required to maintain bodily functioning and growth. Whether this excess promotes or lessens physical and mental health depends upon the way in which it is utilized.

Here is the problem. In most people the tendency to economy of effort has, on the whole, a greater influence on conduct than has the amount of energy and interest actually at their disposal. Unlike children, relatively few adults will tackle a difficult intellectual or practical task just for the pleasure of doing so. The zest of the struggle, the triumph of achieving success in the face of obstacles, the enjoyable release of energy and creative ability can be observed in any normal and healthy 4-year-old, but is all too soon forgotten, and many people go through life with practically no knowledge either of their powers or of the satisfaction to be gained by using them.

Any emotional or physical drive, capacity, or ability which is constructively used brings about an increase in physical and mental well-being. Lack of use is, from the psycho-biological point of view, not a passive but an active state. The surplus energies and drives are *there*—but they are invested in the individual himself. He returns to a state appropriate to physical illness or to infancy, becomes morbidly aware of bodily functioning, and feels ill and helpless. Even this, unfortunately, is not the end of the story, since there are many clinical, pathological, and *x*-ray proofs that the over-investment of energy within the organism sooner or later causes organic dysfunction and "real" illness. The human organism is, then, like the U.S.A. after the last war; sick of a surplus of gold which it could not use.

The country housewife is, I believe, inherently no wiser than the townswoman. The former would be only too pleased to have labour-saving devices, ready-made entertainment, and a fried-fish shop round the corner. If she is more resourceful, ingenious, and competent it is because she has *had* to "make do." She has found Necessity a benevolent if stern goddess; she has achieved mental health in spite of herself and not because she has realized the value of her manifold and often harassing duties. I therefore find some of the trends of post-war planning very disquieting. I am no more in favour of slum housing conditions than I am of monotonous routine work in home and factory, but the constant emphasis on making life easier is distinctly ominous. Broadly speaking, if we plan a post-war world to give us more leisure and less practical problems in our daily life we shall, I believe, plan for mental ill-health.

We are to-day living more simply, working harder, and experiencing greater deprivations than at any time in recent years. We are learning to make and grow what we cannot buy—and, during the war, the national health has improved. Can we maintain this improvement? It is my belief that we shall not do so unless we so plan that the vastly increased output of energy and ability necessitated by war conditions is no less imperatively demanded of us in times of peace.—I am, etc.,

The Tavistock Clinic, London, N.W.3 R. E. LUCAS, M.B.

Medicine and Politics

SIR,—Any trained scientific observer who reads the article under the above title in your issue of May 29 (p. 673) will be forced to the conclusion that its author must have been a politician when very young and had a really bad fright!

A good many doctors with whom I have discussed the matter have confirmed my own experience, that when a practitioner is returned to Parliament for the first time he is greatly surprised at the distrust of the medical profession among the members generally. At first he feels a little hurt, because he knows that he belongs to the most self-sacrificing and public-spirited of professions; but his disquiet is usually short-lived, for he soon discovers that the distrust of the profession is solely the result of ignorance. Should a politician take the trouble to read Dr. Geoffrey Bourne's article he would, I have little doubt, go through exactly the same mental process and reach a corresponding conclusion.

For politicians are very much like other people—no better and no worse. Very few go into politics for purely selfish reasons. They become politicians because they want things done, just as Dr. Bourne is concerning himself with medical politics because he wants something done (or is it something not done?). Most politicians believe that what they are wanting done is for the good of the nation; but some take a more limited view, and are mainly concerned with the welfare of the class to which they belong. But even these believe that what they are trying to do is in the national interest, because they regard their class as of the greatest importance to the nation, and I have no doubt that Dr. Bourne looks upon the doctors in exactly the same light.

It is because politics is only a means to an end and not an end in itself that people of every sort and kind, and with the most varied outlook, find themselves compelled to become politicians. It is absurd, therefore, to generalize about politicians, and consequently such statements as "intellectual activities are not encouraged by politicians" are the most arrant nonsense.

When Dr. Bourne tells us that "history proves that scientific freedom and research are of vastly greater importance to humanity than is administrator" he is on much firmer ground. The administration must undoubtedly take second place, but the value of his work is real; indeed it can be truly said that, in a complicated civilization like our own, the results of scientific research cannot be applied without him. Few of us who are practising medicine can lay claim to the discovery of more than a few of the methods of diagnosis and treatment we use daily; nor is it always possible for us to apply these in accordance with the methods of an exact science. We are compelled, therefore, to act as administrators or politicians, doing the best we can for our patients in all the circumstances of the case. And thus we demonstrate in our daily life that the scientist and the administrator can work successfully together.—I am, etc.,

Northwood, Middlesex SOMERVILLE HASTINGS.

SIR,—In the summing-up of his article on "Medicine and Politics" in the *Journal* of May 29 Dr. Geoffrey Bourne makes a number of points with which most people will agree. The body of the article, however, which is chiefly concerned with a plea for the protection of medical scientific research from political administration, calls for some comment.

Let us suppose that a system of State medicine were introduced. Quite apart from the consideration of whether it might improve the application of existing medical knowledge to the people as a whole, the situation would arise in which ill-health would at once become a *direct* burden on the national income. Even the most ignorant of administrators would be anxious, to put it least charitably, to minimize this burden. In this case the medical profession would have all the cards to play, for the advances in the control and cure and prevention of disease made by medical science are striking enough to convince any chairman, councillor, M.P., or trade unionist—once the facts have been properly presented. (The accusation of ignorance levelled by the medical profession against laymen, though often deserved, is nevertheless largely the profession's fault—for when has it seriously attempted to dispel this ignorance?)

It would be surprising indeed if medical science was not given at least quantitative encouragement under State medicine. As for the quality and freedom of medical science, would the existing places of research be closed and their workers dismissed? Obviously not, nor would those who at present direct or influence research cease to do so. Dr. Bourne, if he expects that State medicine will come, should surely lay less emphasis on safeguards and more on the positive contributions which medical science will make as facilities for it are increased. For freedom must justify itself, and be justified of those who claim it.

It is quite likely (though not certain) that under a State medical system facilities would be more readily available for working on the more common but difficult diseases such as rheumatism, rather than on rare and "interesting" diseases—that is, there would be, in an important sense, a restriction on "freedom" in medical science. Provided that the restriction were relative only it might well be entirely beneficial to the progress of medicine, and, since fundamental processes are not confined to particular diseases, it need not impair the growth of fundamental knowledge.

It is true enough that at present the volume of research done in voluntary hospitals is greater than that in their municipal sisters. Some of the big teaching hospitals have a good tradition in the matter, they have built-in facilities, and they are attached to universities. Where there are whole-time research workers, however, these are usually paid not by the hospitals but by the universities or by the great research foundations. There is no intrinsic reason why such persons should not be attached to county or municipal hospitals. That research is even now carried out quite extensively in these places can be seen by anyone who looks through the sources of papers in the medical press. I myself belong to a county hospital service which has its own active medical society, and its own entirely democratic research committee whose sole aim is to encourage and facilitate research. We can stand up to administrators, for there is fundamentally no conflict of interest.—I am, etc.,

J. H. HUMPHREY.

SIR,—Dr. Geoffrey Bourne claims that medical research is restricted, if not actively discouraged, in the municipal services. This is certainly not true of tuberculosis. The output of original work from State-controlled antituberculosis services, both in this country and in the U.S.A., far surpasses in quantity and is not inferior in quality to that issuing from voluntary institutions. This research is not, indeed, promoted in most instances by the administrators of the service, but is the spontaneous product of doctors' curiosity, set down and worked out in their leisure time. So is the majority of research in general medicine, as reference to contemporary journals will show.

Certain problems do call for high-powered teams with special training and equipment; but investigation in the field is still, and I hope always will be, the part of clinicians with their eyes open, the sum of whose observations can, if so desired, be collected and statistically correlated. Only large organizations can provide the large figures often necessary, and I should like Dr. Bourne to cite any instance where lay members of a local authority have obstructed a reasonable project of this nature. Certainly the Middlesex County Research Committee, which has as its field the county's two million residents, met at its inception no discouragement from its authority, and has so far retained completely that intellectual freedom so valued by Dr. Bourne, tempered by a scrupulous accuracy that he would do well to emulate.—I am, etc.,

BRIAN C. THOMPSON, M.D.

State Subsidy for Medical Education

SIR,—In the letters in the *Journal* concerning a State Medical Service there is one point which your correspondents appear to have overlooked—namely, subsidization of medical education by the State. Immediately after the war, and in any case later, if an unacceptable service is forced on the profession there will be a shortage of doctors. The authorities would no doubt meet this by subsidizing medical education, which in a decade would flood the medical profession with a crowd of docile but undesirable members. A similar method was used after the last war to replenish the ranks of the teaching profession, with, in the opinion of many, unfortunate results. So soon as entry into the profession is made easy, and so soon as one forgets that to be a doctor is "a way of living" and not merely a safe job with a fixed salary, then so soon will medical standards deteriorate.

One other point. One notes repeatedly in correspondence and debates the assertion that State service does not paralyse individual effort, and examples are quoted of outstanding achievements by medical officers in the Forces and in the Colonial medical services; but are not these exceptions? No mention is made of the more usual case of the medical man tied down to an uninteresting routine who, by the time he realizes that he must get out or remain an official for life, finds that his medical talents have passed away and that he is no longer fitted for civilian practice.—I am, etc.,

Knighton. G. H. H. BOOTH.

Selection of Medical Students

SIR,—In the B.M.A. memorandum on medical teaching (June 5, p. 702) I notice that it is recommended that prospective medical students should be interviewed by a small committee to determine if they are suitable "human material" from which to make future doctors. Is this process of selection to be restricted to the medical faculty, or is it logical that it should be extended to law, engineering, science, etc.? If so, where is the freedom of the individual to be found? At present the Ministry of Labour "directs" persons to a "suitable" occupation. Is this the sort of thing we are still to be subjected to after the war? It would seem that the committee's recommendations may extend further than was realized.—I am, etc.,

Rhyl. J. C. L. DAY.

The Raw Milk Danger

SIR,—Papers and correspondence recently have brought to the fore again those two vitally important factors in child health—viz., breast-feeding and the boiling of cows' milk. They can hardly be too often stressed, and though the great majority of the profession are convinced of their desirability, do we insist on them in our own local concerns, or voice our convictions sufficiently loudly?

I am not here concerned with our shortcomings in encouraging natural feeding, but to ask how our consciences stand in regard to milk. That supplied in schools is not compulsorily boiled to start with. Surely we should insist that this is done, except in the few areas where a pasteurized supply is available. And how about hospitals? Is it the rule for all milk to be boiled? No.

Eventually we hope pasteurization will be universal, but until then a lot might be done by school officers and hospital residents if they would just inquire into the state of affairs and protest firmly if they find raw unboiled milk being supplied to the children. The G.P., too, might do more propaganda about this than he does; in fact he sometimes even discourages boiling. What is the conscientious mother to do when her *Nursery World* persistently exhorts her to boil the milk and her doctor says it doesn't matter?

I think one of the reasons for the general lack of realization as to cause and effect in bovine tuberculosis is the doctor's attitude to an established case, say, of glands in the neck. He seldom inquires about the milk supply, but murmurs something to the effect that "there's a lot of this about; children don't get enough butter and fresh fruit these days," unwittingly giving the impression that dietary deficiencies can *cause* the disease. Or maybe he does not like to assert the medium of the infection for fear of upsetting the parents, who may feel he is accusing them of negligence.

Until we make a plain statement (and act accordingly) that every child with bovine tuberculosis has at some time drunk raw milk and that *this* has caused the disease we shall not be doing all that we might to prevent this wholly preventable illness.—I am, etc.,

Stourbridge. JOYCE MCCARTHY.

Aspirin and Gastric Haemorrhage

SIR,—Under "Any Questions?" in the *Journal* of June 5 (p. 714) a question as to whether aspirin can give rise to gastric haemorrhage is answered in the affirmative, and reference is made to the "convincing" evidence brought forward by Douthwaite, Douthwaite and Lintott, and Hurst and Lintott in 1938 and 1939. In the same number (p. 689) Dr. Avery Jones analyses 171 cases of haematemesis and/or melaena recently under his care. Of these, 22 were diagnosed as acute ulcer, 2 as acute gastritis, and in 34 the diagnosis remained uncertain; together these made up 35% of the whole series.

From my experience in hospital and private practice since Lintott and I wrote our paper in 1939, I would expect to obtain a history pointing to aspirin as the direct cause of the haemorrhage in at least one-half of the 58 cases in which chronic ulcer, carcinoma, and cirrhosis of the liver could be excluded. The association is never recognized by the patient himself and is discovered only after a careful cross-examination. It is then found that in a period when the patient is completely free from indigestion he has swallowed one, or more commonly two, three, or more aspirin tablets, either whole or broken into a few fragments, generally with water, occasionally alone, and always on an empty stomach, in order to relieve headache, "rheumatism," or some other pain or discomfort; and that the haemorrhage followed within a few hours. In many cases he has never taken aspirin before or not for many months or even years, and never more than one tablet at a time and then perhaps only after meals. In several instances earlier attacks of haemorrhage could be traced to the same sequence of events—headache, aspirin, haemorrhage. Other proprietary tablets, such as veganin, which contain aspirin, are of course equally dangerous. I have also seen a few patients with chronic gastric or duodenal ulcer in whom the history pointed to the probability that a recent haemorrhage without the usual preliminary digestive symptoms was caused by aspirin.

I believe that the risk of haemorrhage after taking aspirin would be negligible if it were always taken in powdered form and after meals, with 10 gr. as the maximum dose. If all manufacturers of aspirin were to print instructions to this effect on the bottle labels the incidence of haematemesis and melaena in the absence of chronic ulcer would probably be reduced by about 50% and the total incidence by 15 to 20%.—I am, etc.,

Oxford ARTHUR HURST.

Shortened Puerperium

SIR,—Dr. Flew made an admirable reply (June 5, p. 707) to Dr. Denys Smith (May 22, p. 644), who wishes to shorten the puerperium by way of solving the problem of shortage of maternity beds. I should like to support Dr. Flew from many years' experience in maternity and child welfare clinics. Dr. Denys Smith asserts that the majority of working-class mothers who leave the maternity hospitals on the tenth day are "fit and well." I wish he could see some of them a few days afterwards! It is a typical and common experience of mine to be consulted by such a nursing mother when her baby is two or three weeks old, complaining that "my breast milk began to go when I first got about again." She looks pale and anaemic, is obviously debilitated, and I find on inquiry that the lochia are present still and sometimes profuse.

In pre-war days, when the services of a municipal home-help could be procured, it was sometimes possible to get such a patient to bed again in her own home for a few days with excellent results. The lochia would cease, breast-feeding would be re-established, and afterwards she was able to resume her household duties and nurse her baby. Ten days only in hospital is too short a time for the mother who has to return to her home and household duties, with little or no domestic help, if "the normal but considerable processes of involution and repair are to take place," as Dr. Flew says. This applies equally nowadays to many an upper- and middle-class mother leaving the haven of the nursing home for a house or flat—with only fortuitous domestic help.—I am, etc.,

London, W 14. MARY KIDD.

SIR,—I feel I cannot accept Dr. Neal Smith's advice to shorten the puerperium. No definite evidence is offered to show that some cases of prolapse and backache are not due to early rising after labour and quick return to full activity. His reason for keeping mothers in bed at all appears to be on account of heaviness of the breasts until the fifth day. If this is the case, why should mothers stay in nursing homes for as long as a fortnight?

Some reasons for rest in a reclining position for longer than five days after labour occur to me. Throughout the animal kingdom the period following reproduction is one of rest. The stretched pelvic joints, ligaments, and muscles need time for repair, and can hardly be expected to support a heavy uterus while the mother tries to resume an active life. The time taken for this repair must vary with the individual and the type of labour. From my own experience of three puerperia and from questions put to other mothers I have noted that the unsupported feeling about the pelvis takes longer to pass off than any feeling of weakness in other parts of the body, in spite of exercises.

The distended venous system of the lower limbs and pelvis also needs time for shrinkage. To throw extra strain on it by the premature assumption of the erect attitude encourages the formation of thrombosis and emboli, as well as subinvolution of the uterus. The replacement of fluid lost as sweat and blood during labour needs adequate time to allow for satisfactory lactation. Taking the patient out of bed is likely to pool blood in the lower part of the body and so decrease the flow to the breasts. Mild exercises for the arms and upper trunk would seem to be more useful.

Surely in these enlightened days no mother is left lying flat on her back for a fortnight unless she is suffering from some complication which merits such treatment. Most are doing simple exercises by the third day. The cause of mothers rushing to find "supports" is often the feeling of pelvic discomfort described coupled with sagging abdominal muscles and a desire to return to a pre-pregnancy figure. Added to this she finds much encouragement from those around her to get a good corset. Much trouble could be avoided if mothers were plainly told that the feeling will pass off (provided examination shows all is normal). They should carry on with simple exercises, light work, and simple corsets. Rest periods are necessary, and feeding sessions help to provide these. Lifting heavier children until strength is regained should be avoided. Massage with supervision of exercises is helpful if it can be arranged.

I think Dr. Neal Smith is rather unfair to the "well-to-do" mother. She knows she can rest only while she is away from home with the present shortage of domestic staff. She is in a worse position than her poorer sister, who has a smaller house and does not bother so much about appearances, and who does not have to face the difficulties of a professional man's wife, for instance. The poorer mother leading a more communal type of life can more readily call in relatives or neighbours to help, while in larger families the older children look after the younger.

In many cases there is no need for skilled attention after about the tenth day, but mothers should be allowed time to resume their full activity gradually and to be encouraged to continue breast-feeding. There is an urgent need for a really efficient domestic service with priority for mothers, or for special "convalescent" homes. The former scheme which has been envisaged is likely to prove more acceptable, in my opinion.—I am, etc.,

Winchester. MYRTLE M. HUTCHINS.

Advice on Sterility

SIR,—Whilst appreciating Dr. R. H. P. Hick's annoyance about the growth of clinic services (June 5, p. 707) I believe that in this instance the complaint is without foundation.

The contraception clinics at present run by the Family Planning Association can in no way cut across the work of the family practitioner. No patient is seen whose family income exceeds £5 weekly, and before the war very many were wives of unemployed men for whom even the appliances had to be gratuitously provided. Such patients frequently have no doctor of their own, and in these times of "call-up" and evacuation the links are still further severed. It will be among the friends and relatives of such working-class patients that the work on involuntary sterility will in all probability extend.

It is relevant to add that in many cases the family practitioner does not appear to be the most helpful person to approach in such matters. Considerable postgraduate experience is required for the competent fitting of contraceptive appliances, and, with the rapid advancement in the study of sterility, the scope of purely consulting-room advice is inevitably diminishing. There are many women who badly want a pregnancy but who cannot bring themselves to ask their family doctor for advice which they feel to be of such an intimate nature. This is wholly irrational, but undoubtedly true. Although, fortunately, there are practitioners whose skill and interest in such work are second to none, I think Dr. Hick could hardly fail to agree that the majority of heavily worked practitioners are *not* anxious to be consulted regarding problems of a sexual nature. It is a very common experience at clinics to find that patients who have been in the greatest need of intimate advice have received either evasive replies or totally inadequate help from their own doctors. It can hardly be doubted that the family practitioner who is unembarrassed by such inquiries, and willing and competent to deal with them, will *always* be the first to receive his patients' confidence; and, for the rest, the growth of the specializing clinic will be invaluable.—I am, etc.,

London. JOAN MALLESON.

Adder Bite

SIR,—Last year the treatment of adder bite received some prominence in your columns. Clearly the use of specific anti-venom is the ideal treatment, and it is impossible to draw conclusions from a single instance, but the following case seems sufficiently dramatic to justify a further trial if the proper antidote is not immediately available.

A nursing sister aged about 25 was bitten on the instep by an adder at 5 o'clock one afternoon. She was put to bed as soon as possible and hot fomentations were applied at the site of puncture. I saw her at 11 the next morning. By this time the leg was grossly swollen from ankle to knee, with considerable bluish discoloration. The patient stated that the swelling was rapidly spreading and that the leg was throbbing painfully. I advised the application of kaolin poultices and injected 5 c.cm. of heparin intravenously. Within a few hours of the injection the pain had vanished and the swelling had begun to subside. After forty-eight hours the leg was back to normal and the patient allowed up. For two or three weeks the leg was swollen by the end of the day, but apart from that she had no further trouble.

The only other case of adder bite of which I have personal knowledge had acute symptoms for a much longer period and took longer to clear up. This seems to have been the experience of other practitioners with whom I have discussed the matter.

While occupying your valuable space, may I strongly endorse Dr. Bensted-Smith's letter entitled "Houses to Live In," published in the *Journal* of May 8. As a West Country rural practitioner I agree with every word he says.—I am, etc.,

T. M. DAVIE, F/O,
B.M., B.Ch.

Phage for Dysentery

SIR,—In the *Journal* of Dec. 5 (p. 673) is an account of a paper by Col. Fairley on the treatment of bacillary dysentery, and in another recent issue there was a communication from Sir Philip Manson-Bahr on the same subject. Neither of these very experienced physicians even mentioned bacteriophage, and this to me was a very surprising omission.

I will not burden you with statistics, but after 23 years' practice in Alexandria I regard a good bacteriophage as being usually as specific in the case of adults suffering from bacillary dysentery as is antitoxin in diphtheria. I refer to the type of dysentery met with in Alexandria and its neighbourhood, as it is only in this area that I have used bacteriophage. I have no reason to think that the treatment would be less effective with bacillary dysentery elsewhere in the Near and Middle East or even in any part of the world. There is no doubt that for some reason unknown to me bacteriophage often fails in the case of infants and very young children.

As in most illnesses, from a perforated gastric ulcer to a common cold, it is essential to begin treatment without delay. After the lapse of some days, as pointed out by Dr. Compton, one is not dealing with an uncomplicated dysentery but with ulcers grossly contaminated by a very heavy secondary infection with which bacteriophage cannot deal. In my practice I usually get the cases within a few hours of the onset, and it is no exaggeration to say that bacteriophage cures the great majority within 24 hours, often within 6 to 12 hours. Before I began to use bacteriophage I usually paid some 10 visits to each dysentery patient. Now, as a rule, not more than 2 visits are necessary—a considerable annual financial loss to me! I have generally used the bacte-intesti-phage made by the Laboratoire de Bactériophage in Paris under the control of d'Hérelle. But other efficient phages are now available. One ampoule is given every 3 hours, and nothing else allowed by mouth except water. After 1 to 3 doses all pain and diarrhoea have usually ceased and the stools are faeculent and becoming firm. Occasionally 6 to 10 doses are needed. This is the usual story; but it must be acknowledged that even with adults there are a few complete failures where bacteriophage is entirely without effect. I do not think there are more than 5% of such failures. I had one such recently which responded dramatically to sulphaguanidine.

The R.A.M.C. appears to have abandoned the use of bacteriophage. I understand that it was tried on infants and young children in a families' hospital and on patients in a base hospital. I have mentioned above that with infants and small children the results are frequently disappointing; in the base hospital the patients presumably did not start the treatment until a considerable time after the onset of the disease. These facts would account for an unfavourable report on the treatment.

I am entirely in agreement with Dr. Compton that if each regimental M.O. had a supply of good bacteriophage and administered it immediately at the first symptoms of dysentery or enteritis it would very seldom be necessary to evacuate the patient to the base or even to a field hospital.—I am, etc.,

Alexandria. E. N. RUSSELL.

Slow Union of Fractures

SIR,—In a leading article on the slow union of fractures (May 29, p. 669) you state that "there is little evidence that the biological conditions are any different from those of thirty years ago." Yet Sir Robert Jones made the same complaint in 1916 and I answered from the medical and dietetic point of view, and the letter was published in the *Journal*. I pointed out that the same complaint was alleged by the surgeon-in-charge of the Northern Army in the American Civil War—Stimson—so this complaint is as old as the hills.

Biochemists have satisfied themselves that the fault is not in the cells or blood, for the quotient of calcium, iron, and phosphorus is, according to them, normal. Yet I pointed out then that clinically I have commonly seen excessive callus retract and become compact bone after a few weeks' treatment with syrup. ferri phos. co.—Parrish's food—and so take it off structures upon which it was pressing. I have also seen ununited fractures with weak callus become as strong as the proverbial iron when the patient is given this remedy. Furthermore, bruised bone will heal after many months of pain if the same medicine is given.

The only conclusion I can come to is that it is a nervous influence resulting from shock in the less well conditioned subjects, the nerve centres in the spinal cord corresponding to the seat of injury being depressed, and it is the giving of this old remedy that restores the nervous tone. I cannot think of any biological action, such as enzyme formation stimulating the osteoplasts, being the wanting factor, but the fact remains that in general practice I have had success by this method. For example, I had a case of extracapsular fracture of the femur with weak callus which had failed to respond for nine months in hospital, but in which hard callus formed in five weeks; again, a case of fracture of the patella, without capsule, in a woman aged 60, which united in five weeks with free movement. These and many other similar cases of lesser degrees of injury have made such an impression on my mind that I think such a simple remedy might well be given a trial again.—I am, etc.,

London, S.E.1. R. LARKIN.

Mass Radiography and Incidence of Pulmonary Tuberculosis

SIR,—The cogent and timely observation of a practical radiologist of the standing of Dr. J. F. Brailsford on "the grossness of lesion necessary . . . to give radiographic evidence of departure from the normal" (May 22, p. 646) will be warmly welcomed by experienced clinicians who have made an unbiased study of tuberculosis diagnosis in this country during the last thirty years. Equally true is his inference that any radiographic scheme which does not include early cases without radiographic lesion fails to help the tuberculosis service.

To radiograph the whole population and report on 500 films a week, Dr. Brailsford calculates the need for 1,000 units with full staff and 6,000 medical officers. For weekly transport 330,000 buses will be required on an estimate of Dr. N. P. Henderson. This radiologist (Jan. 16, p. 81) wrote that it would take 80 years to examine Greater London at a speed of 100,000 cases a year with one of the present static machines. Dr. Brailsford's demonstration of the immensity of the problem of administration is well appreciated by those of us who are medical members of local authorities. Lay members may be carried away by their own enthusiasm and by the propaganda and the promised Ministry of Health grant, estimated at about £250,000 for 250 machines, and, in select cases, with dependants' allowance. Therein lies the danger of aiding "wishful thinking" by propagating the idea in the minds of the people that at long last tuberculosis will be eradicated.

Fl. Lieut. Evans, in his survey of mass radiography of 75,000 Air Force personnel (May 8, p. 565), detects an incidence of 234 active cases of tuberculosis—i.e., 0.3%—and 387—i.e., 0.5%—inactive cases. In a communication on "Tuberculosis in Recruits" (*Journal*, Aug. 16, 1941) I estimated that of 2,500 examined by me in a year 2% may be considered tuberculous by the average dispensary *x*-ray diagnosis. It is evident, therefore, that the finding of 0.3% active, or 0.8% if the inactive are included, among those passed fit by the medical boards is no criterion of the efficacy of mass radiography, but may be due to the lack of expert clinical machinery at examining medical boards. Evans had the further advantage of continued clinical investigation under compulsory conditions.

Regarding his inactive 0.5% calcified or fibrosed cases, these will be a greater problem for the clinicians to classify and control, especially when it will be remembered that among Australian recruits Cooper found by mass radiography 23% inactive tubercle as against 2.07% by Galbraith. It is difficult to reconcile Evans's figure of 0.8% incidence among fit personnel with the figure of only 112 out of 1,869 recruits—i.e., 6%—referred to the Welsh Memorial Board by the medical boards in Wales (June 21, 1941). In a Yorkshire centre covering a period of three years this percentage was even less, being 4.9%—i.e., 31 out of 457 referred recruits. Full-size *x*-ray films will presumably have been used.

One regrets that the only figure mentioned in the M.R.C. report on "Tuberculosis in Wartime" in the mass radiography section was the 1% tuberculous persons found at a Mitcham radio works, and no attempt was made to marshal all published figures.

I have previously called attention to the fact that although radiography has been increasingly used the diagnosis of tuberculosis has lowered from 51.2% in 1926 to 35.6% in 1938. One reads from the M.R.C. report that 65% of those discharged in the latter year were admitted to tuberculosis institutions as intermediate or advanced cases in England and Wales. The experience of doctors, who are referring increasing numbers of symptomatic cases to tuberculosis clinics, is that a large percentage are either considered negative or inactive since *x*-ray examination has become a routine measure with a decrease in early cases of the type Dr. Brailsford has noted.

His last point—that we have more cases than either accommodation or staff—is equally unchallengeable. Surely if the Ministry of Health by intensive propaganda secures an added 1% or 2% by mass radiography at a comparatively high cost there must be a parallel policy of encouraging local authorities to increase their accommodation and attract staff who will not forsake clinical experience for administrative salaries; otherwise it would seem a case of putting the cart before the horse.

There is much criticism of the efficiency of the doctor in a machine age. With a tendency for the profession to rely more on auxiliary diagnostic methods, clinical instinct and acumen acquired by experience and inspired by the old teaching methods are, unhappily, fast disappearing.—I am, etc.,

Leeds. Z. P. FERNANDEZ.

Treatment of Malaria

SIR,—Quinine, mepacrine, and pamaquin can be combined in numberless ways in the treatment of subtertian infection, but of all methods treatment with quinine alone is probably the least satisfactory. In the *Journal* of April 17 (p. 476) I described a standardized treatment used in my wards at the Seamen's Hospital. The only objection to this scheme is the prodigal use of quinine.

Recently I have treated 11 cases of subtertian infection by two daily intramuscular injections of quinine for 4 days, followed by mepacrine 0.1 g. t.d.s. for 7 days, and, after a short interval, by pamaquin 0.01 g. t.d.s. for 3 days. This course appears to be satisfactory and produces defervescence of fever within a maximum of 72 hours. The amount of quinine used is minimal. The preparation of quinine used is solvochin, which has the great advantage of being almost painless. While the shortage of quinine lasts it is essential that the drug should be given in the most effective and economical way and that synthetic products should be used wherever possible.—I am, etc.,

London, W.1. ALEC WINGFIELD.

Dose of Atebrin in Malaria

SIR,—In all recent articles and discussions on the treatment of malaria with atebrin the dosage has always been given as 0.1 g. three times a day. After using atebrin in many cases it became apparent to me that it had one big disadvantage compared with quinine, and that was that it did not control the pyrexia so quickly.

As, when injection treatment was necessary, one gave 0.3 g. I decided to try larger initial doses by the mouth. I tried it on myself at first and later on others, and have since treated many hundreds of cases with the dosage as follows: first dose, 0.3 g. to be given if possible in the interval between paroxysms—I instruct the patient to take this dose as soon as the sweating stage of a paroxysm is finished; second dose, 0.3 g. given six hours after the first; second and third days, 0.2 g. morning and evening; fourth to sixth day (inclusive), 0.1 g. three times a day. With this dosage the pyrexia is rapidly brought under control, and I have never seen any toxic effects result from it. The total dosage is higher than that originally advocated, as there is evidence that relapses are less common with the higher dosage.

Dr. J. Bryant quite independently came to the same conclusions, and used a similar high dosage, and he reported on this method in an article which was published in the *East Africa Medical Journal*; but it seems to me advantageous that this method should be given wider publicity.—I am, etc.,

R. W. STEPHENSON,
Senior Medical Inspector, Sudan Medical Service.

Vaccination in India

SIR,—I have just seen Dr. C. Killick Millard's letter (Dec. 5, 1942, p. 678). While sympathizing with him on being dubbed an "antivaccinationist," I feel it should be pointed out how dangerous are his statements in his last paragraph, especially in connexion with "universal vaccination" in India. India is "still attempting to do so," but one has only to see the teeming millions of this country to realize the immensity of the problem. Moreover, the position is severely complicated by the rapid deterioration of vaccine lymph under the conditions of heat prevailing in this country. Recently, during the course of a severe epidemic here, I have personally had a dozen cases in a batch of men who were "vaccinated" (under Service conditions) two months previously. Obviously the lymph was useless. On the other hand, a group of Europeans who have lived here for years, and have been vaccinated many times without effect, have recently "taken" with a supply of fresh lymph only a day or so old. Obviously such factors must be taken into account when making statements about the failure of universal vaccination.—I am, etc.,

Jeypore, Upper Assam. JOHN A. LEWIS.

Sir Arthur Newsholme and Russian Medicine

SIR,—In your obituary of Sir Arthur Newsholme (May 29) reference is made to *Red Medicine*, written in collaboration with the late J. A. Kingsbury after a visit to the Soviet Union in 1933. It is stated: "His own impressions of Russia at that time were very mixed. He saw it with some misgiving 'going bald-headed' into a completely socialized medicine, a policy and action towards which nearly every Western country was advancing but by slow degrees."

This summary does scant justice to Newsholme, who provided many of us with our first introduction to the achievements and potentialities of Soviet medicine. Actual quotations give a clearer idea of the general viewpoint expressed in this book. In the preface (p. vii) the authors write: "Soviet Russia has decided that the health of the individual is the concern of society as a whole. Indeed, the Soviet Union is the one nation in the world which has undertaken to set up and operate a complete organization designed to provide preventive and curative medical care for every man, woman, and child within its borders." In the introduction (p. 4) they state that they were forced to the conclusion that "a marvellous reformed and extended medical service had been organized in Russia, the methods and procedures of which the rest of the world would do well to study." And in their concluding observations on the socialization of medicine (p. 309) Newsholme and Kingsbury state that in the U.S.S.R. this "has removed the doctor almost entirely from the field of monetary competition, and has thus abolished a chief source of inadequate medical service. It has made a gratuitous (that is, State-paid) medical service of an astonishingly complete character promptly available for the vast majority of urban populations, a service which is being rapidly extended to rural Russia; and it has given the whole of this service an admirable turn in the direction of social as well as medical preventive measures."—I am, etc.,

P. D'ARCY HART.

Feeding the World's Population

SIR,—It is deplorable that the delegates to the United Nations conference on food and the influential persons who have contributed articles or speeches regarding its aims seem ignorant of the Malthusian difficulty. The world's inhabitants still have a birth rate of 30 or more per 1,000 a year, due mainly to those in Asia, Russia, the Balkan States, and Africa. To have enough for all, they would therefore need to increase their food supply at a rate of at least 20 per 1,000 a year. Can they possibly increase their food supply twice as fast as hitherto? If they could, and did, they would double their numbers about every thirty-five years. However, Sir John Orr has gone far beyond the foregoing Malthusian view by stating that the "world supply of food would have to be increased by about 150 or 200% to maintain the world population in health"—meaning, presumably, even merely its present 2,000 or so millions.—I am, etc.,

Binfield, Berks. B. DUNLOP.

Arsenical Encephalopathy

SIR,—The two articles on arsenical encephalopathy (May 29, pp. 661 and 663) were especially interesting to me in that of the five cases reported four were treated by twice-weekly injections of arsenic and bismuth. This method, of which I was the sole advocate in this country for several years, has now become widely used because of the unfailing serological cure which is effected in primary and secondary syphilis. Cases 1 and 2 in the first article were actually treated for syphilis by me. Case 1 was regarded as of sero-positive primary syphilis, since a penile ulcer was present, but no *Spirochaeta pallida* were found on three examinations by the dark-ground method. The blood Wassermann, originally reported as doubtful, became positive later, and treatment was instituted for sero-positive primary syphilis, despite the inference in the article that this was a case of late latent syphilis.

Another interesting point was the insistence by the authors on the symmetry of the lesions found in the brain. This could be explained if one leans to a belief that syphilis plays some part in the pathology. The lesions of secondary syphilis are characteristically symmetrical, and as most of the victims of this catastrophe are in the 18–22 age group the probability is that the disease is in its early secondary stage. It is an interesting parallel that Milian's erythema and the manifestation of arsenical encephalopathy both occur about the ninth day of treatment.

The apparent increased incidence of this complication would be alarming were it not realized that in the series of cases quoted the hospital authorities concerned were aware that the patient was undergoing arsenical treatment. This is a coincidence that must in the ordinary course of events be unusual, since most patients prefer to keep the knowledge of their infection to themselves. There must have been many cases of coma resulting in rapid death where, in the absence of any history, the possibility of arsenical encephalopathy has never been considered. Unfortunately there is usually no search for signs of acupuncture in the antecubital area in the receiving room.

Those who have been interested in the relative toxicities of mapharside and neo-arsphenamine will not fail to note that in the Liverpool series, quoted by Dr. Glyn-Hughes and his collaborators, three out of the four cases were treated by neo-arsphenamine. For two and a half years in all the Liverpool clinics mapharside has been substituted for neo-arsphenamine in the twice-weekly injection routine for early syphilis, and there has been no evidence to suggest that it is more encephalotoxic than neo-arsphenamine.—I am, etc.,

Liverpool. A. O. F. ROSS.

Obituary

ARCHIBALD SIMPSON, M.B., F.R.C.S.ED.

Mr. Archibald Simpson, one of the best-known practitioners in Shropshire, died suddenly on June 5 at the age of 60. He had practised in Shrewsbury for 32 years and held the following appointments: honorary surgeon, Royal Salop Infirmary; consulting general surgeon, Robert Jones and Agnes Hunt Orthopaedic Hospital; officer-in-charge, Ante-natal Clinic, Shrewsbury; medical officer, Shropshire Technical College of Domestic Science. A native of Edinburgh, Mr. Simpson graduated M.B., B.Ch. in 1905; five years later he acquired the F.R.C.S.Ed. He held house appointments at the Royal Maternity Hospital, Edinburgh, the Darlington Hospital, and the Royal Hospital for Sick Children and Women at Bristol. In the last war he served over-seas in the R.A.M.C., holding the rank of captain.

In the passing of Mr Simpson (writes a colleague) Shropshire loses an outstanding personality. In spite of the natural reserve of the Scot his essential kindliness in practical directions could not be concealed. Most thorough in his attention to patients, he proved himself a real friend and counsellor in serious trouble. His patients showed great attachment to him and confidence in his professional skill and stimulating personality. A man of fine physique, he took an active interest in sport during his brief leisure hours. He was generally admired as an excellent shot; he also distinguished himself as a horticulturist. He is survived by his wife and by his only child, an officer in the Royal Artillery now unfortunately a prisoner of war in Singapore.

A. G. McKENDRICK, D.Sc.ABERD., M.B.GLASG., F.R.C.P.ED.

Lieut.-Col. Anderson Gray McKendrick, late superintendent of the Laboratories of the Royal College of Physicians of Edinburgh and a former director of the Pasteur Institute of India, Kasauli, died on May 30 in Inverness-shire. He studied medicine at the University of Glasgow, graduating M.B., Ch.B. in 1900; he was elected F.R.C.P.Ed. in 1924, and received the degree of D.Sc. from Aberdeen University in 1927. He was a Fellow of the Royal Society of Edinburgh, and the Royal

College of Physicians awarded him the Cullen Prize in 1934. At the Annual Meeting of the B.M.A. in Edinburgh in 1928 he was vice-president of the Section of Tropical Diseases.

The sudden death of Anderson McKendrick (writes W. F. H.) creates a sorrowful blank for his many friends. He was well beloved, and truly one who could bring sage counsel to anyone in difficulty. That was a role which, I feel, he performed for many men. It explains the success of his administration of the Edinburgh Laboratory, of which he was the superintendent for twenty years. He had obtained first place in the Indian Medical Service examination. After a short term of military duty, which included active service on the Somaliland Expedition, he became committed to a scientific career as one of the original members of the Research Department of the Government of India. Most of his work in India was connected with the treatment and investigation of rabies. That led in later years to his appointment to be the League of Nations' statistician for this disease. McKendrick's life is one of those shining examples of a man partially broken down in health continuing to do fine work of a high order. He became director of the Royal College of Physicians' Research Laboratory in Edinburgh and occupied that post for twenty years, a longer period than any of his predecessors: German Sims Woodhead, Noël Paton, and James Ritchie. His research work was of pioneer type—the mathematical, statistical investigation of epidemics, if one can really restrict it to a single subject. But it is even more to McKendrick in his daily life that one gives admiration than to his outstanding ability. His was an upright, broadly religious life, openly avowed. He was a man to be trusted and a guide to both older and younger men. His administration of his laboratory, which should have continued for the duration of the war, had to be discontinued for health reasons, and his few happy active retirement years have not been long enough to see the end of the present world struggle.

OLAF SCHEEL, M.D.OSLO

News has reached London of the recent death, in Oslo, of Dr. Olaf Scheel. Until his retirement in 1940 Scheel was chief physician to the IXth (Medical) Department of the Ullevaal Municipal Hospital, Oslo, which became so well known through the researches on tuberculosis in nurses published from 1928 onwards by Heimbeck, at that time first assistant physician to Scheel's department.

Dr. A. L. JACOBS writes:

Scheel's name is not well known in this country, but it was in his department and under his inspiration that these researches were initiated. Although he generously remained in the background, he made a contribution of first importance to this work, which has had such effect in modifying our views of tuberculosis in young adults. The Oslo workers' discovery of the frequency of primary infection in adult life, and of its close association with the more destructive and fatal forms of the disease, at once stimulated workers in other countries to carry out similar investigations, most of which have amply confirmed the Oslo findings. The practical and factual approach of the Norwegian workers acted like a cold breath of fresh air in the torrid atmosphere of theorizing and speculation which has so clouded our understanding of the pathogenesis of tuberculosis. Anyone who knew Scheel well would at once recognize his part in this salutary influence, for he was a man to whom an ounce of fact was worth a ton of theory.

In Scandinavia Scheel was well known for his emphasis on the importance of environmental conditions, and especially the standard of life, upon tuberculosis mortality. He was also one of the first to initiate the investigations upon university students which have been so widely taken up, and he and Heimbeck introduced B.C.G. vaccination by the intradermal method among students and nurses found to be tuberculin-negative. The results of these researches, notable for their careful statistical control, form a weighty body of evidence of the protective value of the vaccine in young adults, and have led to the use of the B.C.G. vaccine by many other workers in Scandinavia, the U.S.A., and the U.S.S.R. The Prophit Tuberculosis Survey, at present being carried out by the Royal College of Physicians, is modelled on the earlier Oslo investigations.

Scheel had little contact with British medicine, and published only one brief paper in a British journal (*Lancet*, 1937, 1, 922). He was, however, a fine French scholar, very well known among French chest physicians, and published much work in the French journals. At the International Tuberculosis Conference at Lisbon in 1937 he opened a discussion on primary tuberculous infection in adolescence. The last years of his life must have been sadly clouded by the invasion of his country and of France, which cut him off from most of his foreign friends and brought him much personal sorrow. To one who worked in his department and experienced his generous help and inexhaustible hospitality the news of his death brings a sharp sense of loss. There can be little doubt that his name will become better known among tuberculosis physicians in this country when the impact of his work upon tuberculosis theory is fully felt.

Universities and Colleges

UNIVERSITY OF OXFORD

Sir Farquhar Buzzard, Bt., D.M., lately Regius Professor of Medicine and Student of Christ Church, has been elected to an Honorary Studentship at that college.

UNIVERSITY OF GLASGOW

The King, on the recommendation of the Secretary of State for Scotland, has approved the appointment of Prof. James Hendry, M.B., F.R.F.P.S., F.R.C.O.G., of the Muirhead Chair of Obstetrics and Gynaecology, to be Regius Professor of Midwifery, to fill the vacancy caused by the forthcoming retirement of Prof. S. J. Cameron.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Centenary of the Fellowship

In celebration of the Centenary of the Fellowship the President and Council of the Royal College of Surgeons will hold a reception from 8 to 10 p.m. on the evening of Wednesday, July 21, in the Great Hall of Lincoln's Inn (by kind permission of the Treasurer and Masters of the Bench of the Honourable Society of Lincoln's Inn). Some of the newly elected Honorary Fellows will be admitted on the occasion. Owing to the paper restrictions invitations will not be issued to the Fellows of the College, *but those desiring to attend should apply for tickets to the Secretary of the College.* Applications will be dealt with in order as they are received. Day dress or uniform —academical costume if convenient.

At 3 p.m. on July 21 there will be a general meeting of Fellows of the Royal College of Surgeons of England, when various important questions will be under discussion. The agenda of the meeting will be issued at a later date.

At a meeting of the Council held on June 10, with Sir Alfred Webb-Johnson, President, in the chair, Prof. G. Grey Turner was reappointed representative of the College on the Council of King's College, Newcastle-upon-Tyne. The President announced the appointment of Air Commodore P. C. Livingston as Moynihan Lecturer for 1943. It was decided to recognize for the duration of the war the posts of resident surgical officer and house-surgeon at the Connaught Hospital, Walthamstow, for the six-months surgical practice required of candidates for the Final Fellowship Examination.

Diplomas of Fellowship were granted to the following candidates:

A. F. Clift, H. S. Joseph, T. P. N. Jenkins, A. Cavendish, S. Mottershead, K. H. S. Dalliwall, E. R. Davies, C. Brun, R. B. Zachary, R. H. Percival, D. Ranger, H. L. McMullen, E. L. Farquharson, I. A. Page.

Diplomas of Membership were granted to I. M. MacArthur and R. J. T. Woodland.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Physicians of London, to the following candidates:

A. Beck, Una M. Campbell, Maeve Cronin, H. W. L. Dale, D. E. Dunnill, J. C. Easson, G. E. H. Enderby, C. W. Fleischmann, A. J. Fraser-Simson, Evelyn W. Glennie, D. C. Howard, P. T. Merlin, S. E. Osborne, Christine M. Rendell, Helen M. Rossiter, B. A. Sellick, G. H. T. Stovin, H. Q. O. Wheeler.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At a meeting of the College, held on June 4, the following were admitted *as Fellows:* Reginald Hall, M.D., T. M. Kavanagh, M.D., Brendan O'Brien, M.B.; *as Members:* Maude F. P. Bigger, M.B., A. H. Isaacson, M.B., F. F. McKee, L.R.C.P.&S.I., G. S. Prince, M.B.

The Services

The Efficiency Decoration of the Territorial Army has been conferred upon Col. W. R. Ward, late R.A.M.C.(T.A.); Lieut.-Col. (acting Brig.) G. J. V. Crosby; Lieut.-Cols. (temp. Cols.) J. H. Donnelly, D. Mackie, M.C., R. Rutherford; Majors (temp. Lieut.-Cols.) R. O. Brooks, M. S. Good, G. L. Montgomery, E. A. L. Murphy, R. S. Taylor, J. M. F. Whitby; Majors P. Hayes, F. J. L. Lang, R. Pollok, R. V. Powell, all R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Wounded.—Capt. A. R. P. Ellis, R.A.M.C., Capt. M. W. Harvey, R.A.M.C., War Subs. Capt. C. W. Warner, R.A.M.C.

Died of Wounds.—War Subs. Capt. A. Mackler, R.A.M.C.

Medical Notes in Parliament

"In the Discard"

Dr. Summerskill on June 10 asked the Minister of Health on what facts he based his opinion that the implementation of Assumption B by the introduction of a salaried medical service was now in the discard. She further asked how Mr. Brown proposed to obtain the views of the doctors in the Services and those not members of any organization on the future of medical practice, and how he proposed to obtain the views of the people on a State Medical Service and on the extension of the present system of medical practice, respectively, before he issued a White Paper. Mr. Brown said he had repeatedly tried to make it clear that the recently resumed discussions with the Representative Committee of medical men and women were to be regarded as only a preliminary and non-committal exchange of ideas; that he hoped as the next step to publish the Government's appreciation of the main issues involved; and that this publication would afford everyone—including those in the Forces—a full opportunity for open and public discussion before final decisions were taken.

Dr. Summerskill asked why the British Medical Association quoted the Minister as saying that the salaried medical service was in discard. Mr. Brown replied that he was not responsible for what the B.M.A. said. The needs of the people were the primary issue, and there were many other bodies beside doctors to be consulted. More than one Government statement had made clear that what was sought was not a State service but a comprehensive medical service, based on co-operation between the medical profession, the State, and the local authorities. Sir Henry Morris-Jones asked whether Mr. Brown knew that the medical profession repudiated the idea of becoming full-time civil servants. Mr. Brown did not reply.

Compulsory Notification of Venereal Disease

On May 20 Dr. Summerskill asked whether the Minister of Health, in view of the fact that only 1 man and 27 women had been treated under Regulation 33B, would consider the introduction of compulsory notification in order effectively to reduce the incidence of venereal disease. Mr. Brown said he would not take this course. The numbers mentioned by Dr. Summerskill related to persons so far reported from more than one quarter as alleged sources of infection. The figures were not in themselves a true criterion of the efficacy of the Regulation, which, it was already evident, was indirectly doing much to help in getting infected persons to undertake voluntary treatment.

Alien Doctors after the War

Mr. Ernest Brown told Mr. Hannah on May 20 that he could not make any statement as to the policy of the Government for the future of alien doctors allowed to practise under restrictions in this country "for the duration" and anxious, if possible, to continue to serve here or in the Colonies. The arrangements under which certain doctors were temporarily registered under the Medical Acts by virtue of foreign qualifications would cease with the lapse of the Emergency Powers under which they were made.

Nutrition and Child Mortality in Belgium

Answering a question on May 26, Mr. Dingle Foot said that the food shortage in Belgium was felt severely by the child population, but his information did not confirm that, taking the country as a whole, these conditions caused any striking increase in child as distinct from infant mortality. According to statistics recently published in Belgium, there was last year a fall in the death rate of infants under 1 year. The figures for deaths per 1,000 live births were, in 1939, 73; in 1940, 89; in 1941, 85; and in 1942, 78. Medical supplies in the strict sense of the term were and always had been allowed to pass through the blockade.

The Assistant Nurse in Scotland

Mr. T. Johnston, on May 27, moved the second reading of the Nurses (Scotland) Bill. He explained that it varied from the Bill recently passed for England in proposing that assistant nurses should not be recognized in perpetuity, but for five years. This Bill provided that after five years from the commencement of the Act no course of training begun under rules made in the section dealing with assistant nurses should qualify any person for admission to the roll. Another divergency from the English Bill was in Clause 14, which gave power to the General Nursing Council to give a remission, for appropriate cases, in the period of training of nurses who were studying, or proposed to study, for the full certificate under the 1919 Act. If a girl had gone through a year's or two years' preliminary training she should have some remission in the period of training if she intended to sit for her examination again. The Government was not interfering with the standards of examination. Under the principal Act these regulations of the General Nursing Council in Scotland would have to be discussed with the General Nursing Council in England. Every attempt was being made to secure reciprocity. He was not wedded to the precise words of Clause 14. Mr. Johnston went on to say that Scotland had adequate beds and first-class hospitals, but was short of nurses. For tuberculosis they could make arrangements in some emergency hospitals if they had an adequate supply of nurses. They were discussing with certain voluntary hospitals how to affiliate for training purposes some of the splendid emergency hospitals and to rotate through two or more of these hospitals student nurses in course of training. Mr. Mathers welcomed the Bill, but said the College of Nursing had definite grounds for apprehension about Clause 14.

Mr. Westwood, replying for the Government, said there was no intention to reduce the status, training, or qualifications of the nursing profession. Nursing personnel would be required for the extended medical, hospital, and public health services which the Government was now planning. The Scottish Office proposed to draw the attention of education committees to the increased shortage of nurses, and to ask them afresh to interest girls at secondary schools in pre-nursing courses. If this Bill became an Act the Department would urge local authorities to provide pre-nursing courses and continuation classes, and also to ask for further pre-nursing courses at central institutions. Negotiations were being carried through with the hospital authorities for providing facilities to give the proper training to those who were recommended. The Department had had negotiations with the voluntary hospitals.

The Bill was read a second time.

War Casualties

Mr. Attlee on June 1 stated, in reply to Mr. Molson, that the casualties suffered by all ranks of the British Empire Forces during the first three years of war, excluding deaths from natural causes, totalled 514,993. Of these, 92,089 were killed, 226,719 missing, 88,294 wounded, and 107,891 prisoners of war.

Skin Diseases in the Army

Sir James Grigg, replying to Mr. Bellenger on June 1, said he was aware that war conditions tended to increase the incidence of all skin diseases, including dermatitis and impetigo. The steps taken to reduce these diseases included the provision of facilities for ablution and the washing of clothes, the circulation of up-to-date information to all medical officers, medical inspections, and improved facilities for treatment. This included, when necessary, treatment by specialists.

Mr. Bellenger suggested that officers, generally speaking, did not suffer from these complaints, and asked if that was not sufficient indication that there was something from which the men specially suffered—for instance, dirty blankets—which required the attention of the medical authorities in the Army. Sir James Grigg said he thought that was extremely unlikely. He denied that there was something special and unsuitable in the conditions of other ranks which made them particularly liable to these diseases in the Army.

Mr. Rhys Davies contended that dermatitis was increasing among these men when they were in civilian employment before they were passed into the Services. Was it not possible to ask the medical boards to look for these diseases? Sir James Grigg said he would look into that point. His information was that dermatitis was becoming increasingly prevalent in civilian life.

Non-pulmonary Tuberculosis under Government's Scheme

On June 1 Mr. McNeil asked the Secretary of State for Scotland why, in his recently announced scheme of relief for tuberculous patients and their dependants, he had excluded all patients other than those suffering from pulmonary tuberculosis. Mr. Westwood replied that the purpose of the allowances scheme was to encourage people suffering from pulmonary tuberculosis to seek early treatment, not only in their own interest but, since the disease was infectious, in the interests of their families and the general community. The scheme did not extend to persons suffering from non-pulmonary tuberculosis, because the disease in this form was not infectious and did not constitute such a danger to the general public health. Mr. McNeil asked if the danger to other people and not the necessity to treat the sufferer was the main reason for this scheme. Mr. Westwood replied that the main reason was the report of a committee set up by the Medical Research Council, at the instigation of the Government, which recommended these allowances for pulmonary tuberculosis cases and made no recommendation so far as non-pulmonary cases were concerned.

University Grants Committee's Funds.—Mr. MANDER asked the Minister of Health on May 18 whether it was proposed to add to the membership and funds of the University Grants Committee in view of the plans for increased teaching in voluntary hospitals. Mr. ERNEST BROWN replied that it was too early to express any view upon this, pending the report of the Committee on Medical Schools now sitting under the chairmanship of Sir William Goodenough

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* during the week measles notifications fell by 982, whooping-cough by 213, and dysentery by 30, but those for scarlet fever, diphtheria, and acute pneumonia rose by 257, 93, and 88 respectively.

In Staffordshire the notifications of diphtheria and whooping-cough went up by 21 and 32 respectively—the only increases of note in these diseases for the whole country.

Scarlet fever rose sharply in Yorks West Riding 75, Lancashire 46, and Staffordshire 43. Whooping-cough declined, principally in Lancashire by 74, Warwickshire by 63, and Yorks West Riding by 53.

The lower incidence of measles was almost general throughout the country, and particularly in Glamorganshire by 224 cases, Staffordshire by 130, Essex by 118, and Northamptonshire by 101. Norfolk, with an increase of 131, was the outstanding exception to the general trend.

Dysentery was less prevalent in most areas, but in Denbighshire, Wrexham M.B., there were 11 cases. The other chief centres of infection were Lancashire, 27 cases, and London, 13.

In *Scotland* there were 18 more cases of diphtheria, but decreases were reported for whooping-cough 60, measles 52, and dysentery 23.

Diphtheria

The Chief Medical Officer of the Ministry of Health stated at a recent Press conference that 3½ million children had been immunized under the free scheme organized by local authorities, and many had been dealt with by private practitioners. The total proportion immunized was at least 50% of the child population aged 0–15. In an attempt to raise the proportion to at least 75% another campaign is to be launched, which will receive the support of all general practitioners. The death rate from diphtheria at ages under 15 in 1942 was 192 per million population, and was 14% lower than the lowest previous value. The rates for 1939–41 were 228, 266, and 280. Compared with the average of the previous ten years the number of deaths in 1942 was 1,000 fewer, and the notifications were 13,000 fewer.

Registrar-General's Quarterly Returns for Scotland

The vital statistics for Scotland for the first quarter of 1943 show very favourable figures. The birth rate of 18.9 per 1,000 was the highest recorded for a first quarter since 1932, and 101 above the average of the March quarters of 1938–42. Infant mortality was 75 per 1,000 live births: this was 21 below the average of the five preceding first quarters, and was the lowest recorded for the first quarter of any year. The previous lowest rate was 80 in 1938. The number of stillbirths was equivalent to a rate of 39 per 1,000 total births. Maternal mortality was 4.3 per 1,000 live births, or 0.7 below the five-year average for this quarter.

The general death rate was 14.4 per 1,000, being 2.6 below the average of the five preceding first quarters. On only two occasions has a lower death rate been recorded for a first quarter—i.e., 14.3 in 1943 and 14.2 in 1938. The death rate from all forms of tuberculosis was 82 per 100,000 and that from respiratory tuberculosis 63. Both these rates are 4 below the five-year average. The number of deaths from the principal epidemic diseases was 22 more than in the first quarter of 1942, but the rate of 35 per 100,000 was considerably below the average of 88 recorded for the first quarters of 1938–42. Deaths from diphtheria and cerebrospinal fever were 40 and 31 fewer than in the first quarter of 1942, but those from measles, whooping-cough, and influenza were 19, 29, and 48 more.

The boom in marriages after the outbreak of war is declining. The marriage rate during the quarter was 7.5 per 1,000. This is 2.8 below the rate for the corresponding quarter of 1942 and is the lowest wartime marriage rate recorded for any quarter, but is 1.1 above the average for the five pre-war years, 1935–9.

The Week Ending June 5

The notifications of infectious diseases in England and Wales during the week under review included: cerebrospinal fever 79, diphtheria 630, dysentery 125, measles 7,668, acute pneumonia 768, scarlet fever 1,921, whooping-cough 2,144, typhoid 4, paratyphoid 6.

No. 21

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 29.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1943					1942 (Corresponding Week				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

† Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

‡ Includes paratyphoid fever for England and Wales and London (administrative county).

§ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

Medical News

The names of four Canadian medical men were omitted from the list of Birthday Medical Honours published last week at p. 734. Dr. James B. Collip, F.R.S., F.R.C.P., Professor of Biochemistry in McGill University, Montreal, and President of the Royal Society of Canada, was awarded the C.B.E. (Civil); Dr. William J. P. MacMillan of Charlottetown, Prince Edward Island, the O.B.E. (Civil); and Dr. William K. Colbeck of Welland, Ontario, and Dr. Paul C. Laporte of Edmundston, New Brunswick, the M.B.E. (Civil).

Mr. R. Watson-Jones has accepted the invitation of the London Hospital to join the honorary staff as director of the new accident and orthopaedic department which it is proposed to set up. Mr. Watson-Jones will take up his new post on Oct. 1.

A meeting of the London Association of the Medical Women's Federation will be held in the Lounge of B.M.A. House on Wednesday, June 23, at 8 p.m. for a discussion on "State Nurseries: Their Possibilities and Problems." The speakers will be Dr. G. I. Brodie, Mrs. Enthoven, Dr. Marjorie Back, and Dr. Katherine Hirst.

At a meeting of the Middlesex County Medical Society to be held at Grange Park School Clinic, Lansbury Drive, Hayes, on Wednesday, June 23, at 3.30 p.m., there will be a visit to a day nursery followed by a demonstration by the children. Dr. Back will speak on day nurseries, summarizing county experiences. Dr. Wright will describe work done at the school clinic, and the film on modern control of scabies will be shown. Visitors, especially members of the American and Canadian Forces, will be welcome.

National Baby Week, July 1 to 7, is the week in the year when the National Baby Welfare Council (24, Gordon Square, W.C.1) asks particularly that public attention should be focused on the nation's babies.

On the afternoon of Thursday, July 8, the President of the Royal Institute of Public Health and Hygiene will present the Harben Medal to Sir Henry Dale and the Smith Award to Dr. James Fenton.

A national conference on maternity and child welfare, arranged by the National Association of Maternity and Child Welfare Centres and for the Prevention of Infant Mortality on behalf of the National Council for Maternity and Child Welfare, will be held at Friends House, Euston Road, N.W., on July 8 and 9, under the chairmanship of Dr. Stella Churchill. A clinical course for medical practitioners is being arranged by the Maternity and Child Welfare Group of the Society of Medical Officers of Health on the morning and afternoon of Saturday, July 10. Particulars may be had from Miss M. R. Lovelock, 117, Piccadilly, W.1.

Scabies in the County of London becomes compulsorily notifiable from Aug. 1 next. While the existing regulations have done much to counteract the spread of the disease in most parts of the country, it has become evident that in the metropolitan area compulsory notification would help to bring it under effective control and to remedy the conditions which conduce to it.

The New York Academy of Medicine, in co-operation with the State Department of Health, the City Department of Health, and six of the leading voluntary organizations in the fields of maternal welfare and child health, celebrated on February 19 the hundredth anniversary of the publication by Oliver Wendell Holmes of his paper entitled "The Contagiousness of Puerperal Fever."

Early diagnosis and treatment of congenital syphilis were the subjects of two resolutions adopted at a meeting on May 24 of the executive committee of the National Association of Maternity and Child Welfare Centres. In the opinion of the committee the physical and social disadvantages to a child with congenital syphilis are such that everything practicable should be done to diagnose the condition at the earliest possible time, including the routine application of the Wassermann, Kahn, or other tests to the mother's blood during pregnancy, in order that effective treatment may be given. Secondly, the Ministry of Health should give practical effect to this by propaganda, and by stimulating welfare authorities, voluntary hospitals, and clinics.

Drs. F. T. Ingham and R. M. B. Lowis have been officially reported interned, Singapore, and Dr. R. B. MacGregor, Malayan Medical Service, is a prisoner in Japanese hands at Changi Camp, Singapore. Prof. D. E. C. Mekie, F.R.C.S.Ed., has been interned in Changi Camp, Singapore. Dr. Ian Mackintosh of Kuala Lumpur has been officially reported a prisoner of war in Japanese hands. Dr. W. R. Duff of Taiping, F.M.S., is officially reported interned in Changi Camp, Singapore. Dr. C. A. Gibson-Hill has been reported interned in Singapore. Dr. W. J. Tyson, Colonial Medical Service, Drs. F. V. Jacques, R. G. S. MacGregor, and R. A. Macnab have been officially reported interned at Singapore.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W C 1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a m to 5 p m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary

TELEPHONE No.—B.M.A. and *B M J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh

ANY QUESTIONS?

Keeping A.P.T. Cool and Upright

Q.—*Why is it necessary to keep bottles containing A.P.T. for diphtheria immunization (1) upright, and (2) in a cool place? What is the definition of cool? It is not easy to carry such bottles on one's rounds and comply with either instruction, and even the surgery does not provide a place which is always cool.*

A.—1. Rubber used for caps and stoppers is a mixture, and different samples of rubber may be of widely different composition. Some rubbers react rapidly with the antiseptic (usually merthiolate) in A.P.T. Though the immunizing value of the A.P.T. may thereafter be but little reduced, the antiseptic is partly or wholly neutralized—with the obvious risk of bacterial growth in the A P.T. if contaminated during re-use. All rubbers react rapidly at a tropical temperature, slowly in an English climate. It is therefore prudent to reduce contact between the rubber and the fluid to a minimum: hence the manufacturer's advice to store the bottle upright. In most doctors' bags carried during visits it should not be difficult to arrange the bottle in an upright position. If this is not possible, the risk of reaction in the English climate is very small, and A.P.T. issued by responsible manufacturers in rubber-sealed bottles would probably be safe for at least a year. Any reaction would show itself by brownish-black discoloration of the under surface of the stopper or of the fluid. If such discoloration becomes visible through the glass wall, the doctor would be wise to return the bottle at once to the supplier.

2. Almost all sera, prophylactics, and vaccines deteriorate at high temperatures. Since A.P.T. goes to all parts of the world, the advice to keep it in a cool place is obviously cogent for tropical stations. At about 65° F., the temperature of an average room in England, deterioration is very slow. If the bottle is not exposed to real heat —e.g., near a fire or on the floor of a car immediately over the engine on a hot day—A.P.T. will be of satisfactory immunizing power for at least a year and probably two.

Site for Intramuscular Injection

Q.—*The most common site chosen for intramuscular injection seems to be the gluteal region, in spite of certain difficulties and dangers associated with injection into this area. The deltoid and pectoral regions seem to present fewer difficulties. Is there any good reason why more use is not made of these accessible areas?*

A.—Both regions mentioned may be used for intramuscular injection, the main disadvantages being the small bulk of muscle, the inconvenience of persistent soreness in this situation, and the danger of damaging the circumflex nerve. The erector spinae muscle has also been used. The tendency nowadays, however, particularly in the case of the sodium salts of the sulphonamide drugs, is to choose the antero-lateral aspect of the thigh (vastus externus) as the least dangerous site for intramuscular injection.

Analysis of a Hair Preparation

Q.—*A patient of mine is suffering from chronic agranulocytosis, of which I am trying to find the cause. Among other things she has been using a proprietary application for the hair. Have I any power to compel the manufacturers to tell me the ingredients of this preparation?*

A.—The doctor cannot, unfortunately, compel the manufacturers to disclose the composition of the application. He can ask them to give him that assistance *ex gratia*, but they would be likely to refuse, partly because they would be unwilling to disclose a trade secret, and partly because they would wish to avoid giving information which might be used against them in an action for damages. The doctor could not, without the patient's special authority, promise that she would not sue them, and she would be reluctant to waive a right which she might possibly need. If she were bringing an action against them, the court might conceivably grant her leave to administer an interrogatory concerning the composition of the substance; and if the substance is "recommended as a medicine" its composition ought to be disclosed on the bottle (Pharmacy and Medicines Act, 1941, 5, 11). These two possibilities, however, do not help the doctor; but he should not find it difficult to get an analyst's report.

Hypopituitarism, Hypogonadism, Anaemia

Q.—*I have a patient about whom I would welcome suggestions. A man of 50 who has been a farm labourer all his life, he is well covered, but has a parchment-like skin, is childish, and shows signs of infantilism (high voice, small genitals, no beard, and no pubic hair). His intelligence appears to be normal. He has an anaemia (Hb 42%) of an aplastic type unresponsive to massive iron therapy. I am about to embark on liver therapy unscientifically to "stimulate" his marrow. I have never heard of a similar syndrome and would welcome some information.*

A.—Cases of the type described are not excessively infrequent and are often difficult to classify or treat. A group of cases of hypopituitarism associated with achlorhydria and anaemia has been reported by Snapper, Groén, Hunter, and Witts,[1] and two more cases by Witts.[2] In these patients the sequence of events was thought to be pituitary insufficiency → atrophic gastritis → dyshaemopoietic anaemia. The anaemia was of either the hypochromic or the megalocytic type, and responded to iron or liver accordingly. Anaemia with hypogonadism may also occur in dystrophia myotonica and late coeliac disease, but neither of these diagnoses seems likely in the case presented. The most probable diagnosis is anaemia of the aplastic or hypoplastic type directly due to the endocrine defect. Cases of this type are mentioned by Bomford and Rhoads in their important paper on refractory anaemia[3] and have been seen by the writer. Here the sequence is probably pituitary disease → hypogonadism → aplasia of the marrow. Treatment with testosterone propionate, 25 mg. intramuscularly thrice weekly, is well worth trying. If this fails, the patient will probably get along with a large transfusion (1,500 to 2,000 c.cm. packed red cells) at fairly long intervals.

Treatment of Leucodermia

Q.—*Is there any recent advance in the treatment of leucodermia which holds out reasonable prospect of a cure?*

Q.—*I would be grateful for the following information: (a) The aetiology of vitiligo (leucodermia). (b) Is there any modern successful treatment of this condition? (c) Can the condition be inherited? I have a patient aged 24 years suffering from the disease. He feels that a holiday in the sun improves it temporarily, but only on his return home, and not at the time of the vacation. Is this likely? Finally, is suprarenal extract of any avail, and, if so, in what dosage?*

A.—The aetiology of leucodermia remains obscure, so that no rational treatment is known. Recently clinical improvement has been claimed after local treatment with Grenz rays, and this form of irradiation is worth a trial. Otherwise the areas might be rubbed with oil of bergamot and exposed to sunlight, or, for cosmetic purposes, painted with permanganate or with walnut juice. Oil of bergamot sensitizes the skin to sunlight, and some success is claimed for the intradermal injection of gold salts, which presumably act in the same way. This method of treatment lends some support to the view that leucodermia is a local functional disorder of pigmentation which may be corrected by certain stimuli. The effect of a stimulus may not be immediately apparent, and so the benefit of sunshine in vitiligo is usually a late phenomenon. Endocrine preparations of the suprarenal, pituitary, and ovary have all been tried with little result, but as the new fractions are isolated and become available they may be tried experimentally. No guide as to dosage can be given. Rarely leucodermia occurs in several generations, but the majority of cases have no family history of the affection.

Horner's Syndrome after Birth

Q.—*A child was born with blue asphyxia. The cord was tight round the neck, and the result was paralysis of the cervical sympathetic (slight ptosis, myosis, and enophthalmos). The child is now one year old with slight improvement. What is the prognosis? Is there any treatment?*

A.—There is no treatment for a Horner's syndrome of slight ptosis, myosis, and enophthalmos. The condition does not cause any disability, and the asymmetry is likely to become less marked as time goes on. The enophthalmos is more apparent than real, and is really only suggested by the smaller palpebral fissure. As the child gets older there will be compensatory action by the third nerve innervating the levator palpebrae superioris, and also by the frontalis muscle; the ptosis, which is easily overcome by voluntary power, will hardly be noticed. The myosis is unlikely to change much.

Management of Sterile Partners

Q.—*A young healthy woman with a healthy husband married two years ago. She has for economic reasons avoided or prevented pregnancy. She and her husband now wish to have a child, but without success. What is the best advice on treatment to give them?*

A.—The partners in this case should not be considered infertile until two years after they have abandoned the practice of contraception. Until such a time has elapsed no special investigations are necessary. A clinical examination of both husband and wife should be carried out, and if lesions such as underdeveloped testes, retroversion, etc., are excluded they should be reassured. They should be advised against overwork, anxiety, and either too frequent or infrequent coitus. It should be explained to them that the optimum time for conception is the eighth to the eighteenth days of the cycle, and that during this period coitus should be practised every two or three days. A vaginal douche of 1% sodium bicarbonate fifteen to thirty minutes before coitus often facilitates conception, either by softening the cervical mucous plug or by altering the *p*H of the vagina. If after two years there is still no sign of conception, then the case should be investigated fully. It is of the utmost importance that good general health on the part of either the husband or wife should not be accepted as indicative of adequate function on the part of their sex organs.

The semen of the husband, collected preferably by masturbation into a clean dry glass container, should be sent to a pathologist experienced in spermacytology. Undue delay in transit should be avoided if possible, and during transit the specimen should be kept at atmospheric temperature or colder. Heat is to be avoided. A simple examination of a hanging-drop preparation is not sufficient, and a knowledge of semen volume and of sperm density and morphology is necessary to assess male fertility. Huhner's test is useful in some cases. This consists in removing specimens from the cervical canal and from the vagina shortly after coitus, to study the effect of the vaginal environment on the spermatozoa and to see whether the spermatozoa are able to penetrate the cervical plug.

Investigation of the woman requires the services of a gynaecologist, and will involve dilatation of the cervix, endometrial biopsy to determine ovarian function, a tubal patency test either by air or CO_2 insufflation, or uterosalpingography, or both. Estimation of the *p*H of the vagina and cervix may help, but the latter is difficult. The treatment will necessarily depend on the results of investigations, but if the findings are all normal it is to be expected that the dilatation of the cervix and the insufflation will of themselves prove of great therapeutic value. This they do by ensuring better drainage of the cervix, thus preventing the mucous plug from becoming so inspissated as to form an impenetrable barrier to spermatozoa.

LETTERS, NOTES, ETC.

Sterility and Contraception

Mr. V. B. GREEN-ARMYTAGE writes: At first sight it would seem remarkable that the president of the Family Planning Association should advocate the study of sterility in clinics hitherto used for birth control. But maybe this worthy change of heart is not really so paradoxical, for it is gradually being recognized by the public and profession alike that scientific proof now exists for the statement that not less than one-third of the recipients of chemical and mechanical means of contraception in the early months or years of matrimony are eventually and consequentially the complainants of primary sterility. For these the prognosis is by no means so rosy whatever the degree of skill or advice obtainable.

Contaminated Injection

Dr. MALCOLM ALLAN (medical officer of health, Willenhall, Staffordshire) writes: Referring to your annotation in the *Journal* (May 15, p. 608) on the above subject, I found two 25-c.cm. bottles of diphtheria toxoid, alum-precipitated (preservative: ortho-chloromercuri-phenol 1:10,000), which contained a few c.cm. of prophylactic and had not been used for six months. When turned upside down fluid escaped through the rubber caps, and the bottles had been stored in a dusty centrally heated room. I sent both bottles to the laboratory, and the report was in each case: Direct film, no organisms seen; cultures, no growth aerobically or anaerobically.

Tetanus

Dr. E. FISHER (West Wyalong, New South Wales) writes: Referring to Dr. Leslie Cole's paper on tetanus (Nov. 7, 1942, p. 550) I would like to mention that in three cases of tetanus which I have treated the earliest symptom complained of was a feeling of tightness in the upper part of the chest, and tenderness on pressure over the tendons of origin of the sternocleidomastoid muscles. In one instance the patient said he felt as though he had a band around his chest.

IMMUNITY TO TUBERCULOSIS*

BY

G. GREGORY KAYNE, M.D., M.R.C.P., D.P.H.

Tuberculosis Officer, Middlesex County Council

At the outset we should recognize the immensity of the subject and all its ramifications. We may divide it into natural immunity and acquired immunity, or, more correctly termed, natural resistance and acquired resistance. But, considering natural resistance first, we would need to discuss the influence of race, heredity, sex, and age, and even of different organs and tissues; the difference in resistance, if any, to the human and bovine types of bacillus; and, lastly, the mechanism by which natural resistance is effected. The mechanism of acquired resistance, if indeed it is different, offers an equally important problem, as does the hypersensitivity of the tissues which follows infection. How little do we know about the good influence of various environmental conditions on acquired resistance, and perhaps on natural resistance; and, on the other hand, about the bad influence exerted by malnutrition, intercurrent diseases, childbirth, and certain occupations. And this by no means exhausts the list. What part does resistance play in the development of phthisis as seen in the adult? How far do resistance and hypersensitivity determine the protean characters of tuberculous lesions, the varied clinical manifestations of the disease, and its puzzling epidemiological characteristics? And, finally, there are many problems involved in prophylactic immunization.

There is certainly, as yet, no consensus of opinion on the actual cellular or humoral mechanisms of either natural or acquired resistance among those intimately engaged in such research work. But it is possible to indicate the present trend of opinion on the roles of natural and acquired resistance in the evolution of tuberculosis in man, on the connexion between natural and acquired resistance, and on the relations between the latter and hypersensitivity.

Natural Resistance

Natural resistance has been defined as the inherent ability of the body to restrain the growth and bring about the death of the tubercle bacillus on *first* contact with it. It must have been evident for a long time that such inherent ability is present to a very different degree in different species of animals: rats, for instance, are highly resistant to tuberculosis, as are sheep, goats, and horses. But even in regard to man, "constitution" has since early times been considered to be very important in the development of tuberculosis. The discovery of the tubercle bacillus led to a swing of the pendulum, but the soil soon loomed on the horizon beside the seed. The relative roles of soil and seed in relation to the various manifestations of the disease were not, however, clearly discerned. The discovery of the Koch phenomenon in the guinea-pig gave reality to the concept of acquired resistance; and, translated to man, this concept of acquired resistance following infection has for many years been regarded as all-important in connexion with those tuberculous manifestations that develop some time after the primary infection. Thus, while natural resistance might influence the course of the primary infection, the development of later lesions would be determined by acquired resistance. Acquired resistance would act by killing the bacilli freshly introduced into the body at the site of entrance, generally the lung; or, at least, by limiting the effects of the bacilli to the neighbourhood of this site. Moreover, acquired resistance, as demonstrated in the Koch phenomenon, appeared to act through hypersensitivity of the tissues, which developed at the same time. This hypersensitivity was identified with acquired resistance, and the changed state of the body following primary infection was called "allergy," this term including both resistance and hypersensitivity. Hypersensitivity was also held responsible for liquefaction of the so-called reinfection lesions, with resulting cavitation and bronchial spread. But we meet with difficulties at once. Does natural resistance cease to act and acquired resistance take over? If so, at what stage in the development of primary lesions or afterwards does this occur? Or does natural resistance continue to act? In which case, is acquired resistance merely a reinforcement of natural resistance, or does quite a different mechanism operate with the two? And finally, while we might assume that the principle of the Koch phenomenon is valid for reinfection in man from the outside, does it operate against bacilli derived from incompletely healed lesions in the body? We may recall that in syphilis it does not. What part is played by dosage of virus? There is evidence that no natural or acquired resistance will stand up to really immense numbers of tubercle bacilli. But, all other factors being equal, will natural resistance prove more effective than acquired resistance against large numbers of bacilli? All these questions cannot be answered yet, but observations in man during the past 25 years and further animal investigations have thrown some light on the relations between natural and acquired resistance, and on the role of inheritance in resistance.

Racial Resistance

During the last war it was noted that natives from African communities in which tuberculosis is unknown developed rapidly fatal tuberculosis when they came to Europe. This tuberculosis assumed the so-called childhood or primary type—that is, in addition to the lung lesion, extensive glandular involvement and generalization were found. The facile explanation was accepted that this was due to the fact that these natives had not been infected in childhood and had not therefore developed ired resistance. We might, of course, have asked ourselves: if this was indeed the reason, why did not all infected European children die from generalized tuberculosis? However, further observations soon exploded this theory. First there was the work in South Africa among natives on the Rand (Publn. S. Afr. Inst. med. Res., 1932). Although 70% of the natives reacted positively to a very small dose of tuberculin on arrival at the mines they often succumbed to tuberculosis characterized by massive caseation of the tracheo-bronchial glands and extensive caseation of the abdominal glands, liver, and spleen. Yet in 50% of these cases calcified primary lesions were found. Moreover, the disease pursued the same rapidly fatal course whether the reaction to tuberculin was positive or negative on arrival at the mines. On the other hand, it was noted that if the natives stayed in their kraals the disease often remained quiescent. The explanation was offered that the rapidly fatal tuberculosis was due to overwork, undernourishment, and unaccustomed conditions in the mines. But this clearly could not explain it all, since not merely the outcome of the disease but its type was so different from what we see among civilized communities.

---

* Opening paper in a discussion before the Section of Comparative Medicine of the Royal Society of Medicine, held on Feb. 17, 1943.

Then there are the findings in negroes in the U.S.A. The mortality rate among them is three to four times that among the white population. Moreover, Pinner and Kasper (1932), in comparing the pathological characters of tuberculosis in the negro and the white man, found that the primary type of tuberculosis with caseation of the hilar glands was present in nearly one-half of the negro adults. Yet Opie (1924) had shown that the incidence of calcified lesions among negroes is only slightly less than among white men. Here, too, environmental conditions were blamed for the rapidly fatal course of the disease; but, as already indicated when speaking of South African natives, environment could not account for the different type of tuberculosis; and, indeed, comparisons of negro and white populations, when the living conditions of the whites were certainly no better than those of the negroes, showed the same difference. Thus, although the role of environment cannot be entirely ruled out in these comparisons, there can be little doubt that a racial difference in resistance to tuberculosis exists, and that in negroes this difference shows itself by their inability to develop acquired resistance which would alter the character of reinfection lesions. In other words, if a negro overcomes his first infection he behaves to a later introduction of tubercle bacilli into the body as if it were a first infection. Thus the ability to develop and to maintain acquired resistance can form an integral part of what we call natural resistance.

In this connexion it is of interest to mention some observations of Lurie (1928). It is well known that rabbits are susceptible to the bovine bacillus and resistant to the human bacillus. Yet Lurie found that not only do human tubercle bacilli multiply readily in the rabbit but in the first week after inoculation they grow even more rapidly than the bovine organisms. Whereas, however, the human bacilli are soon destroyed by acquired resistance and the animal recovers, the bovine bacilli continue to multiply in the lung and kidneys until the rabbit succumbs to the disease. Therefore, what appears on the surface as the native resistance of the rabbit to the human type of tubercle bacillus really results from a specific resistance acquired during the progress of the infection; for at first no effective opposition to the multiplication of this organism exists. But it may well be asked, Why is this resistance not acquired against the bovine type of bacillus?

Individual Resistance

We have seen that there is evidence for a racial difference in resistance to tuberculosis. It is widely recognized that there are also differences in resistance among individuals of the same race, even among the highly sensitive guinea-pigs. Thus it is not rare to find among tuberculous negroes the typical phthisis of white people. All investigations relating to individual resistance and inheritance are exceptionally difficult, however, because it is impossible to rule out environmental differences. Even the similarities as regards tuberculosis among the identical twins studied by Diehl and von Verschuer (1933, 1937) might be explained by the fact that such twins are more likely than non-identical twins to have an identical environment. Recent experimental work of Lurie (1941) is highly significant in this connexion. He studied the tuberculosis resulting from various modes of infection in generation after generation of six rabbit families inbred by brother–sister or parent–offspring mating and maintained under uniform environmental conditions. The six families fell into three groups—uniformly highly resistant, uniformly highly susceptible, and others intermediate in resistance. The resistance was found to be a function of genetic constitution which by itself determined whether under given conditions of natural respiratory contagion rabbits acquired (*a*) rapidly progressive primary generalized tuberculosis; (*b*) localized chronic ulcerative pulmonary tuberculosis, corresponding to bronchogenic tuberculosis, the common type seen in the human adult; or (*c*) a disease of a character intermediate between these two extremes. It is significant, however, that the resistance even of the most resistant strains could be overwhelmed by large doses of bacilli.

Apart from indicating the hereditary character of susceptibility to tuberculosis, these investigations appear to show that so-called natural resistance as well as acquired resistance may influence the type of lesion formed on first contact with tuberculosis; and thus they lead to the deduction that acquired resistance is but a reinforcement of natural resistance. Some authors in America (Israel *et al.*, 1941), no doubt influenced by these results, have postulated that apparent differences in the clinical manifestations of primary tuberculosis noted between adults in America and those in Scandinavian countries were due to a genetically higher resistance in North Americans. But, in the first place, it has not been established that the so-called different clinical manifestations of primary tuberculosis are really associated with a different pathological picture of primary tuberculosis: the pleural effusions or the apical infiltrations considered "primary" manifestations by the American workers did not occur soon enough after a change in tuberculin reaction to exclude the possibility that they developed after an insignificant but true primary complex. And, secondly, it seems very doubtful if we are justified in applying results obtained in rabbits by mating of an intimacy unknown among civilized human beings to the interpretation of factors influencing tuberculosis in man. Nevertheless, summarizing all that I have said, we may perhaps, on a broad biological basis, consider that resistance to tuberculosis might show itself in the following degrees. The lowest degree of natural resistance will not, on first contact with the bacillus, prevent an extensive primary complex with rapid generalization and death. A higher degree of natural resistance will lead to a primary complex with perhaps some dissemination, and recovery, but no acquired resistance, will follow; so that, as is the case with negroes and South African natives, described above, a fresh infection under bad environmental conditions will again result in a primary complex, this time with generalization and death. A still higher degree of natural resistance will cause a primary complex, recovery from which will give acquired resistance; and therefore any subsequent reinfection will not produce a primary complex but a parenchymatous lesion which tends to liquefy, cavitate, and spread by the bronchi. People still more naturally resistant might conceivably react to a first infection by developing the latter type of lesion at once, as postulated by some American workers. This concept, which, I emphasize, must for the present be considered as largely theoretical, involves one important assumption: that acquired resistance is the same as natural resistance, which it enforces, and that presumably when either natural resistance or a combination of natural plus acquired resistance reaches a certain level, hypersensitivity appears, causing liquefaction and cavitation. One supporting fact to be mentioned is that it is not extremely rare to meet with liquefaction of a primary pulmonary focus.

Allergy

This brings me to the phenomenon of hypersensitivity. The term "allergy," as originally coined, was applied to the difference between the body's response to a second or later dose of antigen (the tubercle bacillus or its products) and its response to the *first* introduction of the antigen. The term has been identified with hypersensitivity as shown in the Koch phenomenon and the tuberculin test. Resistance gained from a primary infection was considered to be due to this hypersensitivity, or at least to run parallel with it and be inseparable from it. These views have been greatly altered as a result of the work of Rice Rich (1936) and his associates. As he puts it: "For many years it has been generally believed that the state of hypersensitivity is the chief mechanism of acquired immunity, the accentuated allergic inflammation having been regarded as the means by which the growth and spread of the bacilli are inhibited. The dangerous and destructive effects of hypersensitive reactions have always been very clearly recognized; but they were believed to be necessary evils that had unfortunately to be borne if one were to possess any acquired resistance at all." Rich, in experiments which are well known, succeeded in separating resistance from hypersensitivity. It has been shown that acquired resistance could be established without concomitant development of hypersensitivity; thus Pagel (1937) states that by treating animals with heat-killed tubercle bacilli he has produced immunity without hypersensitivity; and that (Pagel, 1936) such animals developed bronchogenic tuberculosis (the type comparable to phthisis in the adult) after virulent infection. It has also been shown that acquired resistance of a resistant hypersensitive animal could be transferred passively to a normal animal without concomitant transfer of hypersensitivity; and, finally, that when the hypersensitivity of a resistant animal was abolished by desensitization resistance remained intact. Nevertheless, it is probable that allergic inflammation enforces resistance by bringing to the site of reinfection, more quickly and in more concentrated form, factors that tend to fix the bacilli *in situ* and promote their destruction. It is generally agreed that allergy largely results from stimulation of the tissues by an antigenic component of the tubercle bacillus. Whereas, however, some believe that this component is different from that responsible for the production of resistance, others, like Pagel (1939), consider that hypersensitivity develops when antigen is in excess of antibody, and that this leads to tissue destruction with liberation of antibodies; while resistance due to surplus of antibodies causes no destruction of tissues. At all events, even if allergy is not an essential factor in the mechanism of resistance it appears to have a deep influence on the development of the disease in man.

Mention of the dissociation of resistance and hypersensitivity brings me to the tuberculin test. Allergy or hypersensitivity to the tubercle bacillus should not be identified with tuberculin hypersensitivity. The latter phenomenon appears to be quite unconnected with resistance, and its exact mechanism is still obscure, although our knowledge has advanced as a result of the work of Seibert and her associates. The tuberculin reaction does not represent anaphylactic sensitization to foreign protein, for in the latter phenomenon there is interaction of demonstrable antibodies with antigen, and sensitization of the cell cannot be demonstrated. The tuberculin reaction, on the other hand, is the result of sensitization of the cell itself, and antibodies cannot be demonstrated. The active principle responsible for the skin reaction is apparently protein in nature, and the origin of tuberculin hypersensitivity is connected with the tuberculous lesion; thus hypersensitivity tends to increase with extension of the lesion and to disappear with complete healing. It has even been shown that it is more marked in proximity to the lesion than in the body generally.

In view of what has just been said it is perhaps not surprising that tuberculin tests, both in clinical and in epidemiological work, sometimes give unexpected results. Those who condemn the test on these grounds should at least make sure that they use the purest material available—at present P.P.D.—prepared under rigid standards, and employ similar standards in carrying out and reading the test. Even when all this is done we may still find unexplained variations in the degree of hypersensitivity, or its absence, in persons who have certainly been infected. This should, however, spur us on to further work in order to elucidate this important phenomenon. For it seems clear that it is on the understanding of resistance and related phenomena that the future of tuberculosis control rests.

Mechanism of Resistance

I cannot conclude without referring to the intimate mechanism of resistance to tuberculosis, although I realize that I shall be entering, inadequately equipped, territory much explored yet little charted. Briefly what we have to ask is, What is the fate of the tubercle bacilli, and what part is played in this fate by cellular and by humoral factors? ; and we must ask these questions in regard both to natural and to acquired resistance. According to Pagel (1940, 1942) the fate of bacilli in natural resistance is represented by what happens to them when injected intradermally into the mouse. First the bacilli lose their envelope, being converted from basophilic into eosinophilic organisms; then they become granular and gradually disappear. Or they may remain indefinitely at the site of inoculation without multiplying. The fate of bacilli with acquired resistance, as represented in the Koch phenomenon, is quite different. They disappear rapidly—within a few days or even hours; a few small granules are all that remain. Tubercles form quickly—in from two to four days. The bacillus is now treated as a foreign body that cannot be absorbed, and the tubercles act as a barrier shutting off the bacilli from the rest of the body and the circulation.

Next we come to the thorny and still unsettled question of the relative importance of cellular and humoral factors. Pagel considers that the role of the cells is unimportant, if indeed they play any part at all, in connexion with both natural and acquired resistance. On the other hand, according to Lurie, a very important part is played by the mononuclear phagocytes. Pagel maintains, however, that earlier experiments by Lurie himself contradict this conclusion. At the same time, it must be emphasized that no bactericidal power has been demonstrated in the serum of animals either naturally resistant or made so as a result of infection.

There is one final point I cannot resist making. When I was consulting the Society's *Proceedings* I came across a discussion in 1925 on the control of tuberculosis and the milk supply. I read there the same emphatic evidence that is brought forward to-day by those who appreciate the seriousness of the problem, and, on the other hand, the same arguments against the pasteurization and boiling of milk, and the same expression of difficulties associated with eradicating the disease in cattle. It was more than disheartening to conclude that apparently little, if anything, had been done about it all since then. But I also heard one tuberculosis authority maintain, among others, that he was definitely convinced of the importance of partial immunization against pulmonary tuberculosis as a result of the ingestion of small numbers of bovine tubercle bacilli in milk, and, moreover, that he regarded this as one of the causes underlying the favourable alteration in clinical type and in death rate from human tuberculosis noted in recent years. I do hope that, in view of the present discussions on the safety of the milk supply, this view is no longer held by any responsible member of our professions, and that such travesty of one aspect of immunity will not be allowed to hinder an effective campaign for the eradication of tuberculosis in cattle.

Dr. Charles B. Huggins, professor of surgery at the University of Chicago, has been awarded a prize of $2,000 given by Dr. Charles L. Mayer and administered by the National Science Fund of the National Academy of Sciences. The prize was offered for the most outstanding contribution made during 1942 to present-day knowledge of factors affecting the growth of animal cells, with particular reference to human cancer. The advisory committee decided that this award should go to Dr. Huggins for his studies of the human prostate, with special relation to the cancers taking origin from this gland. A second Charles L. Mayer prize of $2,000 for an outstanding study made in the same field in 1943 will be given, and entries and recommendations for this award should reach the office of the National Science Fund, 515, Madison Avenue, New York City, by Jan. 15, 1944. The advisory committee is interested primarily in fundamental studies on the factors influencing growth of animal cells rather than applications to any particular aspect of normal or abnormal growth.

MILD DEPRESSIVE PSYCHOSIS

BY

B. ANDRATSCHKE, M.D.Prague

AND

C. H. ROGERSON, M.D., M.R.C.P., D.P.M.

(*From the Cassel Hospital for Functional Nervous Disorders*)

In a recent paper upon the health of the doctor, Hope Gosse (1942) gave a table showing the relative frequency of various conditions which had been the cause of sickness of more than seven days' duration in a large group of doctors. The diagnosis "anxiety state" appeared fifth on this list, being more frequent, for example, than appendicitis, peptic ulcer, or cardiovascular disease. Gosse did not claim that this was especially a doctor's disease, so that similar findings might be expected from many other groups of people. The context of his table suggests that the term "anxiety state" was used to cover a wide range of psychiatric conditions not amounting to insanity. His findings agree with the clinical observations of others that functional nervous disorders of this type account for a very large annual wastage through sickness. Indeed, the incidence may be even higher than that stated, since it is notorious that physical diagnostic labels tend to be used in preference to psychological ones wherever possible.

Among the cases thus loosely designated would undoubtedly be found a number of different types. The Cassel Hospital, which was founded to provide treatment for such functional nervous disorders, can furnish from its records evidence of what these types are and which of them are preponderant. A study of these records shows that the majority of cases are grouped under three diagnostic headings. In 1938, for example, out of 137 total admissions there were 45 cases of depression, 35 of anxiety neurosis, and 22 of hysteria. Under all other diagnostic headings together there were 35 cases. Depression was thus the commonest, and it was also the most painful and, owing to suicidal risk, the most dangerous condition requiring hospital treatment.

Lewis (1938) has defined a depression as follows: "Any person who is unhappy and ill with his unhappiness may properly be said to be in a state of depression." In this phrase he has caught the essence of the condition—the symptoms presented by the patient are dependent upon the disorder of mood, which is fundamental. It may be misleading in one sense, however, in that the patient does not invariably complain of his unhappiness but often only of the symptoms consequent upon it. A depression may be said to be psychotic in character, and hence to belong to the group under discussion, when it occurs in the absence of any discoverable psychological trauma, becomes disproportionate to the trauma, or persists unduly when the trauma has ceased to operate.

The treatment of the common functional nervous disorders, including mild psychotic depression, was admirably laid down by T. A. Ross (1937). He dealt most fully with the anxiety neurosis and the hysterical reaction, and his methods still form the basis of the most successful and widely used therapy. Towards depression, however, he was more cautious in his attitude, holding that treatment could increase the comfort of the patient but could not radically affect the course of the illness. Lewis (1934), at the conclusion of his masterly historical review of the subject, expressed similar views:

> "There has been very little written in this review as to therapeutics. Notable as have been the changes in the general care of the insane, there is little to be said about the particular treatment of depressive states. To hinder suicide, to prevent irritation, and to provide for nutrition, sleep, or rest and in due course occupation and interests have long been the objects of judicious treatment, conscious that of the factors potent to heal time is more important than any kind of interference so far attempted."

The position to-day is widely different. The introduction of shock therapy for the treatment of depression has produced a revolution in psychiatric therapy which is still not sufficiently appreciated. In most cases this treatment is capable of cutting short the attack within the space of three or four weeks. It is of outstanding value in the mild non-certifiable types of depression which are so often encountered in clinical practice and in the case material of the Cassel Hospital. Remission rates for all types of depression quoted by various authors—e.g., Hemphill (1942) and Sands and Sargant (1942)—are very high. It must of course be remembered that these cases usually recover spontaneously in the end, but the time and misery saved by effective treatment are very great.

This being so, the early recognition of the mild depressive reaction becomes of the utmost importance, more especially since it appears to be true that the earlier the treatment is begun the more rapidly the remission occurs. Clinical experience in this hospital has led us to the conclusion that in very many cases recognition comes, if at all, much too late. We have therefore felt it advisable to set forth a description of the mild depressive reaction as it has come to our observation, in the hope that it may assist others to detect it.

Survey of 100 Consecutive Cases

It may at first sight appear to be a curious procedure to present a picture of an illness including only so-called mild examples. Our justification is that we have found that these are precisely the cases which present the greatest difficulty and occur with the greatest frequency in general practice. The personality is well preserved, delusions are absent, and the practitioner who has learned to recognize severe examples of the manic-depressive psychosis may fail altogether to recognize these cases for what they really are. It is as if the physician who has observed a severe streptococcal bronchopneumonia should fail to appreciate that a streptococcal sore throat is also a respiratory infection which may require similar treatment. All of our cases were mild ones in the sense that they were not certifiable or acutely suicidal, and they were able to live in the relatively open environment of the Cassel Hospital. In the sense of degree of incapacity produced by the illness they were not in most cases mild at all.

Our survey covers 100 consecutive cases of mild psychotic depression admitted to this hospital between 1939 and 1942. Our aim has been to present so far as is possible a review of the typical history, symptomatology, and characteristic features of the illness in order to facilitate its recognition by the busy practitioner who has little time for psychiatric niceties.

Diagnosis on Admission

It may be of interest to record the diagnoses with which these patients were sent to hospital. The majority were referred by general practitioners or non-psychiatric consultants, a minority by psychiatrists. A diagnosis of depression was made in 25% of cases; 32% were classed as anxiety neurosis, 14% as neurasthenia or psychasthenia; in 15% no diagnosis was proffered. In the other 13% a heterogeneous series of diagnoses were made, including hysteria 4%, schizophrenia 3%, phobia, obsessional neurosis, etc.

Had we any right to assume that in these cases our diagnosis was the correct one? There can be no hard-and-fast criteria in psychiatry, no infallible signs to guide one to the proper diagnosis. On the other hand we had several advantages over our colleagues who referred the cases to us: we were able to study them for a considerable period in detail, we had them under observation for 24 hours of the day, and we received daily reports from a trained nursing staff. Moreover, when there was doubt about the diagnosis the ultimate grouping depended upon the combined opinion of at least three psychiatrists. We believe that, given the same opportunity for observation, our fellow psychiatrists would have reached the same conclusion as ourselves in nearly every case. The problem of differential diagnosis will be discussed later.

Sex, Age, Occupation

Of our patients 56 were males, 44 were females. There is no evidence from these figures of any sex predisposition, a fact which is confirmed by others (e.g., Rennie, 1942). Age distribution is shown in Table I. There is no special occupational bias: employment covers the whole range of occupation usually met with at the hospital. It is, however, noteworthy that with few exceptions all these patients were usefully employed before their illness and were often living particularly full and productive lives. This fact would be less often observed in a similar group of anxiety neuroses or hysterical reactions. Ross has emphasized this point.

TABLE I.—*100 Cases of Depression. Age on Admission and at First Attack*

Age	On Admission			First Attack		
	Males	Females	Total	Males	Females	Total
Under 20 ..	2	1	3	13	5	18
20–29 ..	4	9	13	11	15	26
30–39 ..	12	11	23	14	9	23
40–49 ..	11	12	23	6	11	17
50–59 ..	19	7	26	8	3	11
60 ..	8	4	12	4	1	5
Totals ..	56	44	100	56	44	100

Symptomatology

In Table II are shown the leading complaints of our patients at the time of admission. It will be noted that only 58% actually complained of feeling depressed. Almost all of them subsequently admitted such feelings in response to definite leading questions, but we are here concerned with the spontaneous observations of the patients themselves. Physical symptoms figured among the leading complaints in 78% of cases. There was a variety of such complaints, ranging from insomnia, fatigue, headache, loss of appetite, constipation, palpitation, to all kinds of strange feelings—i.e., tension in the spine, peculiar feelings in the skin, tightness in the head, etc. Only 10 of these patients presented a single physical symptom; in all other cases complaints were made of a number of physical symptoms.

TABLE II.—*100 Cases of Depression. Frequency of Occurrence of Leading Symptoms*

	Males	Females	Total
Physical symptoms	40	38	78
Depression	38	20	58
Fear, anxiety, agitation	30	17	47
Feeling of inadequacy	26	19	45
Feeling of guilt or unworthiness ..	9	10	19
Perplexity or unreality	—	10	10
Suicidal thoughts	4	4	8

Next in frequency came a group of complaints of "fear," "anxiety," "agitation," etc. The most common fear was of becoming insane; other fears were of death, of cancer, of meeting people, etc. Nearly half of the patients complained of a feeling of inadequacy, expressed in various ways—e.g., incompetence, the mind not working as it formerly did, inability to carry on with duties properly, etc. Feelings of guilt and unworthiness—of not being good enough for one's family, of having committed terrible mistakes, etc.—occurred in 19%. Feelings of unreality or perplexity were found in 10%: it is interesting to observe that these patients were all women. Suicidal thoughts were mentioned in only 8% of cases, but, as with the complaint of depression, many more had experienced such ideas than mentioned them at the first interview.

Absence of hallucinations, delusions, etc., is to be explained by the nature of the group of cases we are here studying.

Previous Personality

A study of the previous personality of our patients reveals some interesting observations. Though the descriptions were recorded by a number of different observers working largely independently, three groups of cases emerge quite clearly. The first and largest contains 44 patients, all of whom were described in terms stating or implying overconscientiousness and a tendency to perfectionism in all their actions. Of these, 12 were also possessed of great drive, and were as a rule definite leaders in their own sphere; 7 were also described as timid and fearful, and these were on the whole overwhelmed by their own conscientiousness. The second group contains 13 patients whose normal personality was gloomy and pessimistic; in addition they were more or less hypochondriacal. In contrast to these two groups was a third, totalling 11 cases, in which the personality was described as cheerful, "outgoing," and either placid or active. It is worth noting at this point that out of a total of 9 manic attacks in the life-histories of the whole series 7 (each single attacks) occurred in this small group. These were in fact evidently the true manic-depressives, whose physique and temperament have been described by Kretschmer (1936). Unfortunately we have not sufficiently reliable data on the physique of these patients.

The rest of our series was a heterogeneous one including 8 whose previous personality was frankly inadequate, 5 unstable psychopaths, 2 paranoiacs, and 17 in whom no special features were noted.

Precipitating Factors

Precipitating factors, mainly of psychological but to a small extent of physical or mixed origin, were found in 82% of cases. These figures correspond closely with Rennie's observations. Psychological factors were represented by conditions or events which would place a special strain upon the individual. In Table III distinction has been drawn between acute psychological stress or trauma—in our cases mainly the death of a parent or marriage partner—and chronic psychological stress, which seems to play a more important part, being present in 62 cases. The commonest sources of such stress were business and professional worries and marital difficulties.

TABLE III.—*100 Cases of Depression. Precipitating Factors*

Chronic stress* alone	38
Plus acute stress	10
Plus physical disease	14
Acute stress alone	11
Plus physical disease	4
Physical disease alone	5
Total with precipitating factors	82
„ without known precipitating factors	18
Total	100

* "Stress" = psychological stress.

Physical disease, either alone or in connexion with acute or chronic psychological stress, appeared in 23 cases. Of these 7 had focal sepsis in teeth, tonsils, or sinuses, 9 had had influenza, and two presented degenerative cardiovascular disease. There were no examples of frank endocrine disorder, though involutional factors were thought to be present in 5 cases.

The war as a source of chronic stress (i.e., aggravation of business or personal worries, anxiety and loss of sleep due to air raids) played an indirect part in 26 cases. In 2 cases it appeared to be directly responsible through the patients' personal experience of an air-raid disaster.

History of Previous Attacks of Depression

Out of the 100 cases 51 had had one or more previous attacks of depression before their admission to hospital. The figures are necessarily approximate, since one often had to rely upon the descriptions given by patients or their relatives. The age at onset of all first attacks is shown in the second part of Table I. The peak occurs in the 20–29 age group. A surprisingly large number of first attacks happened at or before the age of 20. With one doubtful exception all these occurred after puberty. Of the 61 patients over the age of 40 admitted to hospital 33 had had previous attacks. This figure corresponds closely with clinical experience, and it may be said with confidence that of all patients over 40 seen in an attack of depression at least half may be expected to have had one or more previous attacks.

Family History

Findings concerning family history are shown in Table IV. They are based upon 83 cases, since in 17 no record of the family history was found. Records concerned first- and second-degree relatives, with the addition of data about first cousins

TABLE IV.—*100 Cases of Depression. Analysis of Family Histories*

Recorded histories	83
With abnormality	62
Without „	21

Disorder	Total Cases Recorded in 87 Histories	Rate per 100 Family Histories
Depression	13	15·7
Suicide	14	16·9
In mental hospital	18	21·7
Neurotic, unstable, etc.	44	53·0

in two cases. For convenience the number of abnormal individuals per 100 family histories is presented in column 2 of the table. It will be observed that the number of relatives who have had a serious attack of depression, had been in a mental hospital, or had committed suicide is such as to give a combined rate of 54.3 per 100 family histories. This figure may convey some idea of the degree of taint in the family histories of cases of depression and of the frequency with which positive findings may be anticipated.

Differential Diagnosis

We are now in a position to build up the picture of a typical case of mild depression as it may be met with in clinical practice. Among the commonest positive features are the following:

The patient may be of either sex and any age past puberty. In three-quarters of the cases one of the leading complaints will be of physical symptoms, nearly always multitudinous and often rather unusual. In approximately half the cases there will be a complaint of depression, anxiety, or feelings of inadequacy, often of all these things. In half the cases the patient will have been of a conscientious perfectionist nature—very often before his illness a successful individual, though occasionally overwhelmed by his own conscientiousness. Three-quarters of the cases will show definite precipitating factors of a psychological kind. Chronic stress will be found much more frequently than acute disaster. About a quarter of the cases will present physical precipitating factors; among these, sepsis and influenza are worthy of note. Half the patients over 40 years of age will have had a similar attack in the past. The family histories will frequently include one or more relatives who have had an attack of depression, have been in a mental hospital, or have committed suicide.

In addition to these positive findings there are certain others which are very characteristic of the depressive attack but less easy to present in statistical form. There is often a tendency towards a diurnal rhythm: the patient is worse in the morning and better in the afternoon or evening. Insomnia is common; the patient can usually get off to sleep promptly, but awakes very early. Loss of weight, amenorrhoea, and lack of sexual feeling are also frequent. The weight curve is usually a reliable guide to the progress of the attack. Lastly, the depressed patient tends to have a special attitude towards himself and his symptoms. He feels so unworthy that he almost apologizes for taking up the doctor's time. This is in marked contrast to the neurotic patient, who generally revels in his own symptoms and expects the physician to be as interested in them as he is himself.

The above positive findings, taken singly, will not furnish much evidence of the nature of the attack, but where several are found in one case (and their frequency is such that more than one is likely to be found in each case of depression) they provide strong pointers to the correct diagnosis. Since, however, no mere mathematical sum of clinical facts is sufficient in itself to enable one to arrive at a diagnosis it is necessary to add certain observations of a more general character.

Anxiety neurosis was the diagnosis most frequently made before admission. Indeed, complaints of anxiety, agitation, and fear were often so prominent as to mask the underlying state of depression. The genuine anxiety neurosis tends to be of two types—an acute form in which each individual attack of anxiety develops abruptly, lasts for a few minutes or a few hours, and then dies away; and a more chronic form, often termed neurasthenia, in which smouldering symptoms of anxiety are almost constantly present. In both types psychodynamic factors can always be found which have an immediate cause-and-effect relationship to the anxiety symptoms. In the acute type the situation in which the attack occurs, or some association which that situation arouses, is usually pregnant with meaning for the patient and provides the clue to his repressed fears. In the chronic type there may be a more diffuse and complex cause for the symptoms, based upon faulty mental habits, with unhealthy attitudes towards himself, excessive timidity, etc. In both types depression occurs as well as anxiety, but it also is dependent upon situational factors—in contrast to the mood of a true depressive psychosis, which is far less affected by environmental changes.

In the history of a typical anxiety neurosis the symptoms will be found to have a gradual progressive evolution in the life history of the patient. The neuroses have been termed by Gillespie (1942) "disorders of social relationships," and this phrase illuminates most aptly their essential distinction from psychotic depression, which is an illness occurring as a more definite and circumscribed entity in the life history of an individual who at other times may appear relatively well adjusted.

The differential diagnosis from schizophrenia is usually evident from the bizarre nature of the symptoms in this condition and the previously shut-in nature of the schizophrenic personality. Difficulty chiefly arises at the two opposite poles of adult life—in adolescence and at the involutional period, when depression often assumes an unusual character. Discussion of these problems, however, belongs to the psychiatric textbooks.

It is necessary to bear in mind that depression produces a lowering of the whole psychic efficiency of the individual, so that, for example, obsessional symptoms may make their appearance. When such symptoms occur in attack form it is always wise to consider the possibility of an underlying depression.

Course and Treatment

It is difficult to predict the probable duration of an untreated attack of depression. A few cases clear up very quickly, lasting only a few days or a few weeks. The majority last for several months, a few very much longer. In the present series the longest duration was 7 years, and there were one or two others with a duration of 3 or 4 years.

Without shock therapy remission is generally a gradual process. The weight begins to improve, appetite to return, insomnia to lessen. There are often brief spells of cheerfulness to break the gloom, which seems by contrast all the worse. Indeed, it is sometimes then that suicidal risk is greatest, particularly as the power of decision is returning to the mind. Occasionally there is a sudden abrupt remission in some quite incongruous situation. Occasionally also there may be a swing over to a state of elation and excitement. Minor hypomanic episodes are fairly common, but they are usually transient and easy to handle. More severe examples are rare in this group, as may be inferred from the fact that there was a history of only 9 manic attacks during the previous life of all these patients. The misery which these patients experience during their illness has in the past only served to emphasize the inability of the physician to provide any specific remedy. General measures as emphasized by Ross and by Lewis have played their part as in many other conditions, but recovery, when it has occurred, has often been ascribed by the patient to some quite fortuitous circumstances.

There can be little doubt in the minds of those who have observed any considerable series of results that convulsion therapy provides the means, so long sought, of cutting short the attack of depression. The theoretical basis for the treatment is almost non-existent. It was introduced by von Meduna for the treatment of schizophrenia. Experience suggests that it is in fact not the treatment of choice for schizophrenia, but that it should be reserved mainly for depression. Cardiazol was at first used to induce a convulsion; but it is unpleasant for the patient, and the risk of fractures during treatment is considerable. Electric-shock therapy, credit for the introduction of which to this country must be shared between Fleming, Golla, and Grey Walter (1939) and Shepley and McGregor (1939), is rapidly superseding it. This method is without unpleasantness save for the transient disturbance of memory, and the risks are very slight. At this hospital, for example, about 400 convulsions have been induced during the past 12 months without serious misadventure. The majority of mild depressions, even those of several years' duration, are relieved by 3 to 8 convulsions, administered twice weekly. In many cases the improvement after two treatments is dramatic in the extreme.

In suitable cases treatment can be undertaken in the out-patient department or consulting-room. However, there is one point that must not be overlooked: treatment is not finished when the attack of depression has been overcome. The majority of cases have had some important psychological precipitating factor. It is necessary to attempt to deal with this factor, lest relapse occur speedily. This may require quite extensive psychotherapy or, more commonly, an attempt to instil into the patient's mind certain principles of mental hygiene which he had previously ignored. The importance of the constitutional factor must not be forgotten; but this should only emphasize the need for the patient to live within the limits of his capacity. There is no evidence that convulsion therapy has any power to prevent the recurrence of depression in the future. Experience over many years has, however, taught us that mental hygiene, sensibly applied, can greatly influence the probability of relapse.

ABNORMAL AGGLUTINATION REACTIONS OF A STRAIN OF LEPTOSPIRA ICTEROHAEMORRHAGIAE

BY

J. C. BROOM, M.D.

Bacteriologist, Wellcome Research Institution, London

AND

H. C. BROWN, M.B., D.T.M.&H.

Major, I.M.S. (ret.); Pathologist, Cambridge Hospital, Aldershot

Proof of the diagnosis of Weil's disease (spirochaetal jaundice) depends in most instances on serological investigation. It is often impossible to differentiate this condition, on clinical grounds alone, from infective hepatitis (catarrhal jaundice), and only on rare occasions are leptospira seen in the blood or isolated by culture or guinea-pig inoculation during the first few days of the disease. Most commonly, Weil's disease is suspected because the patient, by vocation or chance, is brought into contact with rats (e.g., working in sewers, damp mines, fish-markets; immersion in canals or stagnant pools). Confirmation is obtained from the blood count, which in Weil's disease shows a polymorphonuclear leucocytosis; and proof is furnished by the presence in the serum of increasing amounts of antibody to *Leptospira icterohaemorrhagiae.*

The agglutination test is generally used to detect the presence of antibodies, and the specificity of the reaction has been well established, although care is needed in the choice of strain, preparation of antigenic suspension, and interpretation of results (Brown and Broom, 1939). In our case, for routine tests we chose, after a considerable amount of experimental work, a strain of *L. icterohaemorrhagiae* (Jackson), which we isolated in 1934 from a London sewer-worker suffering from Weil's disease. Cultures of this strain, grown in Fletcher's rabbit-serum-broth medium and formalinized to 0.2%, were used for eight years. This strain proved satisfactory throughout that period as judged by the correlation between the agglutination results and the clinical histories, blood pictures, and (in positive cases) the occasional isolation of leptospira from the blood or urine of patients.

Recent Abnormal Reactions

During the autumn of 1942, however, the sera of 34 cases of jaundice admitted to the Cambridge Hospital, Aldershot, were found to agglutinate this strain of *L. icterohaemorrhagiae* although there was nothing in the history of these patients to suggest that they were suffering from Weil's disease. In addition, differential blood counts were either normal or showed a relative mononuclear increase, as occurs in infective hepatitis, instead of the polymorphonuclear leucocytosis characteristic of leptospirosis. Nevertheless, these sera produced a true agglutination of *L. icterohaemorrhagiae* (Jackson). The agglutinated clumps, examined by dark-field illumination with a 1/12-in. objective, proved to consist of leptospira, thus differing from the false agglutination referred to by Brown and Broom (1939). During the course of the disease in these patients the agglutination titre of the serum rose to a limited extent (titres of 1/300 were not unusual) and then disappeared completely in a few weeks. In true Weil's disease the titre commonly reaches 1/10,000 to 1/30,000, and remains demonstrable, though at a lower level, for years after recovery.

The occurrence of a positive agglutination and the rise in titre during the disease suggested the possibility of atypical Weil's disease. Centrifuged deposits from the urine of patients between the fifteenth and twenty-third days of disease were examined microscopically by dark-field illumination, and were scarified into guinea-pigs by Lieut.-Col. N. T. Whitehead, R.A.M.C. All precautions were of course taken to examine as fresh urine as possible; and alkalis were administered to the patients to render the urine slightly alkaline. Blood taken from patients during the first ten days of the disease was also inoculated into guinea-pigs. In no case were leptospira seen and no guinea-pig became infected.

Protection Tests

The serum from cases of Weil's disease will normally protect guinea-pigs against infection by a virulent strain of leptospira. Pooled serum from six of the Aldershot cases was therefore injected intraperitioneally into guinea-pigs, each animal receiving a single dose of 5 c.cm., 2.5 c.cm., or 1 c.cm. The same doses of known anti-leptospira serum were given to another series of guinea-pigs. All the animals, and also controls which had received no serum, were inoculated with 0.5 c.cm. of a virulent culture of *L. icterohaemorrhagiae* (W.P.R.L. strain). The temperature of each animal was taken and recorded daily.

The results of this experiment were unusually clear-cut for a protection test. The anti-leptospira serum protected all the animals, none of which showed even a rise of temperature. The control guinea-pigs and all those which had received the pooled Aldershot serum showed the accustomed signs of leptospirosis in guinea-pigs—namely, temperatures mounting to 106° F. followed by a sudden fall to subnormal, and terminated by death between the fifth and seventh days. Post mortem the appearances were typical, and leptospira were seen in microscopical preparations from the livers.

Further Tests

Additional serological tests were carried out with other strains of *L. icterohaemorrhagiae*—namely, one human strain (Coppard) and two rat strains (Wild Rat and W.P.R.L.), all of which agglutinate well with anti-leptospira sera. The sera under investigation failed to agglutinate these strains. In addition, the adhesion test described by Brown and Davis (1927) was applied to these sera. The same strain (Jackson) which gave the spurious original agglutination results was used, but as a living, not a formalinized, culture. The adhesion test was consistently negative with these sera. These serological tests were carried out in duplicate, independently, in London and Aldershot, and only insignificant quantitative differences were obtained by the two workers.

It is apparent, therefore, that formalinized suspensions of this particular strain have become unduly sensitive to sera of certain cases of jaundice other than Weil's disease. The effect is not caused by the presence of bile in the serum reducing interfacial tension, because serum from a number of cases, including twelve of arsphenamine jaundice, produced no agglutination.

It seemed possible, therefore, that the result might be due to an altered protein ratio of the serum. We had intended to carry out protein-fractionation of all sera, but unfortunately pressure of other work rendered this impossible. However, to test this point with serum the protein ratio of which was known to be altered, blood from 25 patients suffering from various diseases which produce a high red-cell sedimentation rate was kindly supplied to us by Dr. J. M. Alston. Only one serum agglutinated *L. icterohaemorrhagiae* (Jackson); the others were all negative. The positive serum was from a child with a rheumatic condition; but after a few days in hospital he was removed by his parents and lost sight of.

There was no suggestion, therefore, that the protein changes which produce high E.S.R. are responsible for the agglutination.

Abnormal Behaviour of L. canicola

At this stage in the investigation a paper by Das Gupta (1942) appeared in which he stated that a particular strain of *L. canicola* had recently become agglutinable by normal human serum. Das Gupta found that this non-specific agglutination did not take place if the serum were heated to 56° C. for half an hour before use.

This abnormality differs from the one we have described because the suspensions of *L. canicola* were agglutinated by normal serum. However, we retested several samples of the sera under investigation against the Jackson strain after they had been heated. The agglutination titres were reduced but not abolished. This reduction of titre is not due to destruction of complement, because sera which had been held at room temperature for periods up to six weeks still produced agglutination, and after that time no complement could have been present.

Reversion of L. icterohaemorrhagiae to Normal

The leptospira suspensions with which these investigations were carried out were prepared from serial subcultures of the strain, and the aberrant agglutinations occurred with the different lots in use from Sept. to Nov., 1942. Later in November it was realized that no further sera which were without effect on the other strains were agglutinating the Jackson strain. Samples of four sera which previously agglutinated the strain were still available and were retested. Now they also produced no agglutination. Since that time some 50 additional sera have been tested, but no further cases of non-specific agglutination have occurred. The suspensions, however, are still agglutinable to full titre when tested against immune rabbit serum.

Discussion

The agglutination of one strain of *L. icterohaemorrhagiae* by a number of sera which were negative with other strains, and the abrupt cessation of the phenomenon, seem to point to some temporary instability of this strain. It is of course well known that the agglutinability of strains varies greatly, and this strain was chosen because it agglutinated well. The medium used for culturing leptospira contains rabbit serum, and it sometimes happens that the serum of certain rabbits appears to retard rather than enhance the growth. Also, some apparently satisfactory cultures fail to agglutinate with specific antiserum. It might be argued, therefore, that some abnormality of the medium had produced unduly sensitive suspensions, whereas later subcultures in normal medium had reverted to their usual stability.

On the other hand there is the undoubted fact that the serum from only a proportion of cases of infective hepatitis gave positive results with these suspensions, and this seems to suggest that the sera possessed some unusual constituent which reacted with an abnormally unstable suspension.

Summary and Conclusions

More than 70 cases of jaundice occurring during the autumn of 1942 have been investigated. Of these, the sera of 34 agglutinated the strain of *L. icterohaemorrhagiae* (Jackson) that had been in use for eight years as a diagnostic antigen

These "positive" sera failed to produce adhesion with the same strain, failed to agglutinate other strains of *L icterohaemorrhagiae,* and failed to protect guinea-pigs against infection with a virulent culture of leptospira.

No leptospira were seen in the deposits of the centrifuged urine of these cases. Scarification of the deposits and inoculation of blood into guinea-pigs failed to produce infection

Differential blood counts done on these patients were either normal or showed a relative mononuclear increase instead of the polymorphonuclear leucocytosis characteristic of Weil's disease.

The non-specific agglutinations are different from the false positives we have previously described. In our opinion they are due to an acquired abnormal susceptibility of the strain used as the antigen.

This instability was lost on further subculture, and the strain has apparently reverted to normal.

There must have been some additional factor present in the serum, because the sera of only a proportion of cases of jaundice produced this agglutination. Such an occurrence makes it necessary to employ cultures of more than one strain for diagnostic purposes.

We feel that this is an additional argument in favour of the view we have previously expressed that "until some method of standardizing cultures of leptospira is employed, the serological diagnosis of Weil's disease should be undertaken only at laboratories where the idiosyncrasies of the antigens are well known."

We wish to express our thanks to Col. W. H. O'Riordan, *M.C.*, O.C. Cambridge Hospital, Aldershot, and to Lieut.-Col. N. T. Whitehead, *M.C.*, R.A.M.C., assistant director of pathology, South-Eastern Command, for placing every facility at our disposal during this investigation.

SYMPTOMATOLOGY OF MALARIA

BY

P. H. BIRKS, M.R.C.S., L.R.C.P.
Captain, R.A.M C.

Since April, 1942, I have been medical officer to a unit heavily exposed to malaria. During the hot months we had many cases of acute febrile malaria, 80% of which were malignant tertian infections. Hyperpyrexial, cerebral, and bilious forms were encountered, and one quickly grew accustomed to the vagaries and complications of malaria in its acute forms, and later to the so-called chronic malaria with its enlarged spleen, anaemia, and general ill-health.

With the onset of the cold weather fresh cases rapidly diminished, although I was faced with a large number of patients with relatively trivial complaints whom I at first treated on conservative orthodox lines according to their symptoms, but with no success. Headaches and pains in the back were evidently not English aches and pains. Dismissing the possibility of malingering by reason of my personal knowledge of the patients, I remembered that the largest pathological factor in this part of India was malaria, and, having access to a microscope, I began a general investigation of all cases reporting sick.

I hope, by recording the following cases, to show that malaria is something more than an acute febrile disease, and that it can produce such varied symptoms as pains in the back, rheumatic pains about joints, pains in the testicles, urticaria, multiple conjunctival ecchymosis, cardiac irregularity, recurrent diarrhoea, and obstinate eczematoid conditions without fever. I cannot say dogmatically that these symptoms and malaria are direct cause and effect, but I suggest that there is weighty evidence in favour of this, having regard to the positive blood examinations and the results of treatment.

Case Records

Case 1.—Complained of severe pain in the back, worse at rest than when walking about; no history of malaria; treated for several days as lumbago with liniment and mist. sod. sal. without improvement. A thick blood film showed B.T. rings and trophozoites; the spleen was not palpable though the splenic area was dull to percussion. A standard course was given and all symptoms disappeared on the third day of treatment.

Case 2—He had severe pain over second costal cartilage on left side. This appeared swollen and was tender on pressure. There was also clinical evidence of anaemia and general ill-health. A thick blood film revealed M.T. rings; the spleen was not palpable. After a course of standard treatment all symptoms disappeared.

Case 3.—This patient had severe pain in left side of chest over fifth, sixth, and seventh ribs, worse on breathing. There was no fever and no physical sign in the chest. The tip of the spleen was palpable, and a thick film revealed M.T. rings and crescents. All symptoms subsided after a standard course.

Case 4.—Complained of recurrent swellings of the face; there was no history of any previous allergic phenomena. A blood slide revealed B.T. rings and trophozoites. After a standard course no further swellings occurred. A previous similar case had been seen in a patient with recurrent benign tertian malaria. This man had urticarial swellings of face and over both tibiae and above the ankle-joint.. A third case showing B.T. rings has also been seen.

Case 5.—He developed a patch of dry scaly eczema with occasional formation of vesicles and pustules just above the left knee; other less-marked but recurring areas of dry scaling with erythema were apparent on the flexor aspects of the arms. Exposure to sun aggravated the condition. The spleen was not palpable, but thick blood film showed M.T. rings and crescents. There was evidence of anaemia. After a standard course the patches of eczema subsided for the first time over a period of three months.

Case 6.—He had clinical malaria four months previously and showed a large conjunctival ecchymosis. B.T. rings and trophozoites were found in thick film. No fever was present. Acute conjunctivitis with enlarged superficial blood vessels has also been seen which failed to respond to treatment on orthodox lines. M.T. parasites were found in thick blood film. The condition cleared after standard treatment. A third similar case of this type cleared very slowly under silver nitrate drops. Later, B.T. rings were found in the peripheral blood.

Case 7.—Complained of palpitation, and on examination a gross irregularity of pulse was found with dropped beats corresponding to extrasystoles, heard on auscultation of the heart. The irregularity disappeared on exercise. Thick blood film showed B.T. rings. After rest and standard treatment no further irregularity was detected. The spleen was not palpable.

Case 8.—Had pain in the left shoulder, slight pain in the right shoulder and left hip. There was low fever, 99° to 100°; the pulse rate was 120 standing and 90 lying. An apical systolic murmur was heard. A diagnosis of rheumatic fever was made, but a thick blood film showed M.T. rings. After a standard course he was restored to normal health.

Case 9.—Complained of pain and swelling in testicle. Right testicle swollen and acutely tender on palpation. Low fever 99° to 100°, headache, and malaise. A blood slide revealed M.T. rings and crescents. A standard course was given and the symptoms subsided rapidly. On rectal examination prostate normal; prostatic massage yielded only a little clear fluid; vesicles not palpable.

Case 10.—This is one case of many which showed identical symptoms—i.e., profound lassitude, frontal headache, and loss of appetite. No previous history of malaria. Thick blood film showed M.T. rings and crescents. There was evidence of anaemia. A standard course restored him to normal health.

Case 11.—Another example of several similar cases. Acute diarrhoea responding to intestinal sedatives but relapsing immediately these were withdrawn. There was loss of weight and appetite. Examination of the stools produced no microscopical evidence of disease. A thick blood film showed M.T. rings, and the diarrhoea responded to standard treatment.

Discussion

These cases suggest that the malarial parasite can exist in the peripheral blood and produce diverse pathological conditions without pyrexia.

The efficacy of treating a whole unit with antimalarial drugs —e.g., blanket treating—has been known for a long time, but with a supply of drugs that is not unlimited this is wasteful. Instead of indiscriminate "blanketing" it would be better to treat selectively, choosing any man obviously below normal health, where possible checking each case by thick blood preparations. It is a shibboleth that parasites cannot be found except in febrile cases. M.T. rings and B.T. trophozoites and rings can be found if the same diligence is used in searching a thick film as is necessary in thin films. The crescent, too, can be seen, though it is often too distorted for confident diagnosis.

Manson-Bahr describes a physical sign which I have found most useful as confirmatory evidence of malaria. In health the conjunctival blood vessels are few in number, pale-coloured, and of fine calibre; in other acute fevers they are often multiple and arranged radially, giving the eye a hazy pink appearance. In malarial infections, acute or afebrile, vessels of deep red colour and greater width can be seen winding a tortuous course on the surface of the conjunctiva. They are not especially numerous, nor is the whole of the conjunctiva necessarily involved. I have seen an extensive ecchymosis spread from one of these vessels during acute febrile malaria. If this can happen here it is probable that it can happen on any mucous membrane or indeed in any part of the body, and it offers an explanation of many of the obscure symptoms that may be encountered, such as the common throbbing frontal headache.

I submit that our conception of malaria as an acute fever is only one half of the truth and that it is also a generalized disease of arterioles and capillaries capable of producing a multitude of symptoms relative to the state and site of these vessels without any accompanying fever.

My acknowledgments are due to Brigadier McLeevey, who kindly read and approved this paper for publication.

GAS INFECTION OF THE BRAIN AS ONE FORM OF THE SERIOUS COMPLICATIONS OF CEREBRO-CRANIAL INJURIES

REPORT BY A COMMITTEE OF SOVIET SCIENTISTS (162)*

It is sometimes difficult to explain the various forms of serious complications arising from cerebro-cranial injuries. Very often these injuries run a different course in respect of the onset of granulation, conclusion of healing, and types of complications, in spite of the fact that they have the same localization, the force damaging the cranium is the same, and the missile is similar. The whole series of acute meningo-encephalitic complications which occur in the first stage of evacuation, in the F.M.H. (Field Mobile Hospital) of the first and second lines, attract attention and demand explanation.

It is now generally accepted that injuries sustained in the present war, including cerebro-cranial ones, are mostly infected. The range of pathogenic organisms infecting the wounds is very large. Gunshot and explosive missiles are in the majority of cases causing badly lacerated, contaminated, and consequently infected wounds. Data collected by Soviet authors and published during the civil war proved that the majority of cerebro-cranial injuries were caused by shell fragments, mines, etc.—not bullets—resulting in blind tracks, with retained pieces of clothing, dirty hairs, etc. Bullet wounds, particularly penetrating ones, were in the minority.

The Infective Organisms

We undertook investigations with the consent and support of the Chief Military Medical Directorate of the Red Army. We carried out intensive and detailed bacteriological examination of cases of cerebro-cranial injuries, and came to the conclusion that they were infected with the same micro-organisms as muscular injuries. Sterile wounds were rare: from 300 cases only 2 were registered as sterile. Of cases of cerebro-cranial injuries 61.7% were infected with cocci (*Streptococcus anaerobius*, *Str. pyogenes longissimus*, *Str. pyogenes longus*, *Str. brevis*, *Staph. pyogenes aureus*, *Staph. pyogenes albus*, micrococcus, diplococcus, *Gaffkya tetragena*, etc.).

Of our cases 20.5% were infected with putrefactive aerobes (*Bact. megatherium*, *Bact. mycoides*, *Bact. mesentericus*, *Bact. subtilis*, *Proteus vulgaris*, *Kurthia zenkeri*). 11.2% were caused by gas-producing anaerobic organisms, the great majority (94%) being *Cl. perfringens*; next came *Cl. oedematiens* (12.1%) —in only one case was there *Cl. oedematis maligni*. 6 2% were caused by putrefactive anaerobes—*Cl. sporogenes*, *Cl. putrificum*, *Cl. butyricum*, and *Cl. tetanomorphum*. *Cl. perfringens* is usually found in cerebro-cranial injuries in combination with putrefactive anaerobes, aerobes, and streptococci.

Table I gives comparative percentages of various organisms in cases treated in the F.M.H. during 1½ months after the injury; in cases transferred from other hospitals 1½ to 2 months after the injury and treated in the neurosurgical clinic of the Institute of Experimental Medicine; and cases treated in the Institute of Experimental Medicine 1 to 1½ months after the injury and receiving a course of sulphonamide therapy.

TABLE I.—*Percentages of Various Organisms*

	F.M.H.	Neurosurg. Clinic	Sulphonamide Therapy
Pathogenic anaerobes ..	13%	6%	9%
Putrefactive anaerobes ..	15·5%	18·3%	2·6%
Putrefactive aerobes	38%	50%	13 1%
Pathogenic streptococci ..	35%	41%	7·9%
Various cocci	75 52%	80%	94·7%

The figures in the table show that the more serious types of infection are met with during the first few days; later some of the patients die, and in some the pathogenic organisms disappear and are replaced by non-pathogenic ones (cocci). In neglected wounds the percentage of putrefactive organisms increases. The local use of sulphonamides accelerates the process of clearing the wound of pathogenic organisms.

---

* Translated by A. Fry, M.R.C.S.

The part played by infection in penetrating wounds of the skull is very great, as the percentage of fatal results with anaerobic infection (gas gangrene) is high (Table II).

Table II.—*Percentages of Fatal Results*

Type of Infection	All Cases	Cases in F.M.H.
Pathogenic anaerobes .. .	33%	50%
Putrefactive anaerobes .. .	16%	15·4%
Putrefactive aerobes	6·5%	12·8%
Cocci	0·4%	1·5%

Although the general mortality due to coccal infection is the lowest it differs for various cocci: the most pathogenic are *Str. pyogenes longissimus* and *longus*; the mortality due to these in the F.M.H. is 3.1%, whereas the percentage of fatal cases due to all the other cocci is *nil*.

The healing process is also influenced by the type of infection in a way similar to Table II. Two cases with sterile wounds had healthy granulations on the eighth day, and scarring began on the eighteenth day in spite of the depth of the cerebral damage (5 cm. and 8 cm.). In 14 cases of penetrating and non-penetrating cranial injuries infected with staphylococci and micrococci the wounds were sterile about a month after the injury. Of 12 cases of infected non-penetrating cranial injuries 7 were sterile in the same period. Of 20 infected penetrating cranial injuries only 2 were sterile. Putrefactive aerobic infection gave sterile wounds in 4 out of 16 when the dura mater was not damaged, and 2 out of 16 when the injury was a penetrating one.

Of the greatest interest for us were the cranial injuries infected with spore-forming organisms (anaerobes). The clinical course of such cases varies, and there are four different forms: (1) acute; (2) subacute, 1 to 2 months; (3) chronic, 2 to 4 months; (4) latent. The last form comprises those cases which have a favourable clinical picture but in which pathogenic anaerobes continue to be isolated from the wound. We had 6 such cases, and in 2 we found *Cl. perfringens*, which was lethal for certain animals (white mice).

Table III gives the mortality and the favourable results of gas-gangrene-infected cases in the four clinical forms.

Table III

	Acute	Subacute	Chronic	Latent
Total cases	10	9	14	6
Died	8	4	5	0
Favourable result ..	2	5	9	6

Cultures taken from heart, liver, spleen, wound, etc., 10 to 24 hours after death have grown *Cl. perfringens* pure or in combination with *Cl. sporogenes*, *Cl. putrificum*, and *Cl. oedematiens*. Cultures grown post mortem have shown the presence of the same micro-organisms as during life. All facts proved that the cerebro-cranial wounds were the source of sepsis. All tests for the virulence of infection were performed on white mice weighing 40 to 50 g.; the culture used was 18 to 20 hours old, and the dose 0.3 c.cm. by intramuscular route into the thigh. The organism was afterwards verified post mortem from the animals' organs by growing it on Wilson and Blair's medium.

The high percentage of deaths from pathogenic anaerobic infection of cranial wounds proves the great virulence of the organisms. In the 39 cases of anaerobic cerebral infection there were found:

Cl. perfringens	in 36 cases	Cl. tetanomorphum	in 12 cases
„ oedematiens	„ 4 „	„ butyricum	„ 11 „
„ sporogenes	„ 15 „	„ tertium	„ 1 case
„ putrificum	„ 13 „		

The clinical picture of infection of the brain by gas-forming anaerobes is characterized by the following signs and symptoms: (1) gas gangrene; (2) discharge of necrotic brain tissue and debris from the wound; (3) colourless, watery, purulent discharge; (4) acute and putrid smell of the wound; (5) formation of gas in the wound; (6) oedema; (7) prolapse; (8) meningitis; (9) low temperature with rapid pulse; (10) abscesses; (11) severe "bursting" headaches; (12) blood picture (increase in number of lymphocytes and high sedimentation rate); (13) nausea and vomiting; (14) depressed state of patient; (15) general appearance; (16) delay in formation of granulation.

In the acute form we find: gas gangrene, discharge of necrotic brain tissue and debris, gas formation in the wound, acute and putrid odour, oedema, prolapse, severe bursting headaches, frequent septic complication, and death. In the subacute and chronic forms there is first of all gas formation in the wound; then watery discharge, acute and putrid odour, oedema, prolapse, and gangrene; later, sometimes after the external healing of the wound and apparent cure, there appear metastatic abscesses of anaerobic aetiology and meningitis, followed in some cases by death. In the latent form, to which belong all carriers—particularly of *Cl. perfringens*—there is a slow progress of wound-healing without the characteristic symptoms of gas-anaerobe infection.

In view of the fact that the carrier rate of gas-infection micro-organisms was found to be 11.2% in cases of penetrating injuries of the skull, the majority of which resulted in gangrene, it is obvious that this affection is very common. Our most important, and vital, task is therefore to lower the mortality rate of gas gangrene, and the means to achieve it are as follows:

1. The use of prophylactic anti-gas-gangrene serum in doses of 5,000 to 10,000 units.

2. The timely use of sulphonamides—locally and as an emulsion in castor oil or cod-liver oil (10 g. sulphanilamide, 10 g. sulphathiazole, in 80 to 100 c.cm. of castor oil); sulphathiazole orally 6 g. daily for 6 days; intravenously, 1% solution of sulphathiazole 30 to 40 c.cm. two to three times in 24 hours.

The facts about the action of sulphonamide emulsion will be discussed in a separate article.

For the better illustration of our suggestions about the conduct and treatment of gas infection of the brain we append abstracts of some of our cases.

Acute Form (Gas Gangrene of Brain)

Cases Ending Fatally

Case 1.—Wounded March 15, 1942; died March 23. There was a transverse wound in the right temporal bone 4 by 9 cm.; brain tissue was protruding from the wound, which was partly gangrenous and had an offensive odour. On the day of death the following signs and symptoms were noted: general state grave; unconscious; some dark-red brain matter was discharging and some gas bubbles were apparent in the wound. Necropsy showed considerable gangrene of the temporal region of the brain. Bacteriological findings in the wound and at necropsy were *Cl. perfringens* and *Cl. sporogenes*.

Case 2.—Wounded March 7, 1942; died March 31. An extensive brain lesion was found on trephining. The brain and dura mater were pulped and there was about 5 c.cm. of brain debris. Offensive odour. Grave condition of patient. Necropsy: semifluid mass with debris in the posterior part of the right cerebral hemisphere, with sero-purulent fluid and offensive smell. On section the cerebral cortex showed considerable loss of definition. Bacteriology: From wound while patient was alive—*Cl. perfringens* and *Staph. pyogenes longus*; at necropsy—the heart, liver, and spleen contained *Cl. perfringens*, the pathogenicity of which was confirmed on animal inoculation.

Case 3.—Wounded March 3, 1942; died March 7. Bone fragments, pieces of cap, and skin with hair were extracted from the depth of the brain wound, which was 7 cm. long. The discharge was dirty and purulent, and consisted of necrotic cerebral tissue with an offensive odour and gas bubbles. Condition grave; bursting headache; unconsciousness Necropsy showed extensive gangrene of brain tissue and loss of cortical definition. Bacteriology: From wound discharge—*Cl. perfringens, Cl. sporogenes, Cl. butyricum, Bact. mycoides, Proteus vulgaris*; at necropsy—*Cl. perfringens* and *Cl. sporogenes*.

Cases with Favourable Issue

Case 4.—Wounded April 3, 1942; a cranial bony defect 1 by 1 cm. was found during operation, with herniation of cerebral matter. A cavity was present in the temporal lobe from which gas escaped with a whistling sound and about 10 to 12 cm. of brain debris with purulent odour. The cavity was packed with emulsion of sulphanilamide and sulphathiazole. Condition grave; severe headache. Bacteriology: *Cl. perfringens, Cl. sporogenes, Cl. putrificum, Str. pyogenes longus*. April 3: On removal of the packing there was a sharp purulent odour. April 8: Absence of cerebral pulsation. April 11: Cerebrospinal fluid appeared from the wound. The emulsion of sulphanilamide and sulphathiazole in castor oil was applied on April 8, 11, 15, 20, and 23. The general state of the patient improved considerably during that period; the formation of gas in the wound stopped; the prolapse of brain tissue disappeared together with the sero-purulent discharge; granulation began. Bacteriology: *Cl. perfringens* isolated on April 12. On April 20 no more were seen. The culture of the organisms from the wound proved very virulent to animals. The patient was under observation until July 15, when he was discharged from our clinic.

Case 5.—Wounded on March 11, 1942. He was operated on on March 20, being in a very serious condition. There was a cranial defect between the parietal bones from which gangrenous portions of the brain and free bony fragments were protruding. The lesion was 6 cm. deep. There was about 15 c.cm. of putrid discharge with brain debris. The cavity was packed with our compound emulsion. March 23: Oedema of soft tissues of scalp; right-sided paresis and unconsciousness. Bacteriology during March 22 to 30: *Cl. perfringens, Cl. butyricum, Str. pyogenes.* Locally, sulphanilamide and sulphathiazole emulsion in castor oil was applied on March 23, 26, 30, April 3, 6, and every third day afterwards; orally, sulphathiazole, 4 doses of 1 g. on March 21, 22, 23, 24, 25, and 26. On March 26 the characteristic symptoms and signs of gas infection ceased. The patient's condition remained serious till April 5. April 9: Considerable improvement in patient's general condition: lively cerebral pulsation, granulation, amount of purulent discharge considerably lessened. Cultures from the wound on April 12 and 15 showed absence of *Cl. perfringens.* Patient remained in the clinic till April 20, when he was evacuated in good condition to the base hospital. Cultures of *Cl. perfringens* from the wound proved very virulent to animals. The rapid change in improvement in favourable cases is very characteristic of the acute form of gas infection (gas gangrene of the brain).

Subacute Form

Cases with Fatal Result

Case 6.—Wounded Feb. 22, 1942; died April 27. At the operation performed by us on March 12 at the F.M.H. we found, on enlarging the bony defect in the skull, a necrotic region of the brain and tracks in the frontal direction 7 cm. and in the occipital direction 4 cm. long. A dirty-coloured fluid with brain debris of offensive odour was found in those cavities. Cultures showed *Cl. perfringens.* An emulsion of 1 part of sulphanilamide and 2 parts of sulphathiazole was used locally throughout. General condition of patient grave; prolapse of cerebral matter; bursting headache; semiconsciousness; offensive sero-purulent discharge; later meningitis; at the end progressive cerebral abscess. At necropsy *Cl. perfringens* was found in the cerebral abscess and various organs.

Case 7.—Wounded March 3, 1942; died April 6. Muscular rigidity in the beginning; copious discharge; prolapse of brain tissue; bursting headache. Compound emulsion used throughout. Bacteriology (March 10): *Cl. perfringens, Bact. megatherium, Kurthia zenkeri,* streptococci. Signs of cerebral abscess appeared at the end of March. *Cl. perfringens* was isolated post mortem.

Case 8.—Wounded March 6, 1942; died May 4. Prolapse of cerebral tissues; gas bubbles; penetrating wound of left parietal region with necrosis of temporo-parietal cerebral regions; *Cl. oedematiens, Cl. sporogenes, Cl. putrificum.*

Chronic Forms

Fatal Cases

Case 9.—Wounded Dec. 21, 1941; died April 29, 1942. Diagnosis: penetrating wound of right temporal region. Condition during the prolonged period—serious. Operation was performed on Jan. 23. Fragments extracted from the cerebral wound. Subsequently there was a profuse offensive purulent discharge; meningeal symptoms; neck rigidity. Bacteriology (Feb. 2): *Cl. oedematiens, Cl. perfringens,* staphylococci, streptococci, *Proteus vulgaris.* Local application since Feb. 3: sulphanilamide and sulphathiazole 1:2 in vaseline oil; sulphanilamide solution intravenously; orally, sulphathiazole 1 g. six times daily for 5 days. Condition on Feb. 6 satisfactory; on Feb. 10, good. On Feb. 13, 17, 26, and March 19 no micro-organisms were found. On March 3 granulation started. However, towards the end of April symptoms of progressive cerebral abscess began, accompanied by meningitis, and on April 29 the patient died. Necropsy: Abscess in right temporal lobe; purulent meningitis. Bacteriology: *Cl. perfringens* from the abscess, blood, and spleen; *Cl. oedematiens.*

Case 10.—Wounded Jan. 23, 1942; died April 20. Until Feb. 15 Vishnevki's ointment was used. Feb. 15: Operation, when non-pulsating prolapse of brain was found. After excision of the prolapse, puncture of frontal and temporal lobes was performed, when pus with gas bubbles was obtained. A fistulous track covered with cerebral tissue was observed in the temporal direction. 20 c.cm. of pus was found. The wound was filled with 20% emulsion of sulphanilamide and sulphathiazole 1:2 in castor oil. The bursting headache improved after the operation. Bacteriology of discharge (Feb. 16 to March 3): *Cl. perfringens, Cl. putrificum, Cl. sporogenes, Cl. tetanomorphum, Cl. butyricum*; together with staphylococci, streptococci, *B. coli.* March 12: No more pathogenic microorganisms. March 17: Wound sterile, with healthy granulation and little discharge. March 23: Good general condition. From the beginning of April, however, the condition got worse: severe headache; right facial paralysis, rigidity, positive Kernig sign. Cerebral abscess was diagnosed. Patient operated on again, but died from heart failure. Bacteriology of brain post mortem: *Cl. perfringens,* which, although it disappeared from the wound while the patient was alive, caused the cerebral abscess, which proved fatal.

Cases with Good Result

Case 11.—Wounded Nov. 27, 1941. Diagnosis: comminuted wound of skull penetrating the cranial cavity. Vishnevki's ointment was applied until Dec. 17. Dec. 17: Discharge of brain debris with profuse offensive purulent discharge. Jan. 22, 1942: Operation. Bacteriology: *Cl. perfringens, Cl. oedematiens.* From Feb. 25 anaerobes disappeared. Emulsion of sulphanilamide and sulphathiazole in castor oil was used locally from Feb. 9. March 7: Condition good; patient was then evacuated to a base hospital.

TABLE IV.—*Results of Experimental Work on Animals infected with Gas Gangrene of the Brain*

Experiment No.	Animal	Infection Route	Dose of Infection c.cm.	Infecting Organism	When Died	Cultures Obtained	Post-mortem Findings

	,, 15	,,	0·05				

Case 12.—Wounded Dec. 1, 1941. Diagnosis: penetrating comminuted wound of temporal region of skull. Vishnevki's ointment applied till Feb. 10; from Feb. 10 sulphanilamide and sulphathiazole. Condition: December, serious; January, less serious; from Feb. 14 patient felt much better. In March, evacuation to the base. Bacteriology on Feb. 4 showed *Cl. perfringens.* No pathogenic organisms after Feb. 13.

It is evident, in the subacute and chronic forms of anaerobic infection of the brain, that if the disease progresses without metastases (cerebral abscess) the prognosis is good; but if metastases of anaerobic origin appear the result is serious.

Case 13.—Wounded Dec. 24, 1941. Feb. 18, 1942: Operation; intracerebral abscess found, cavity 6 cm. deep. Bacteriology (Feb. 18, 24, March 3, 16, 26, 31): *Cl. perfringens* virulent to animals tested March 23. Culture on April 11 was already less virulent. In spite of the findings the general state began to improve after March 30 Granulations appeared on March 3

Discussion

It is obvious that the symptoms and signs of gas gangrene of the brain in all its forms depend on several causes—virulence of the anaerobe, type of trauma or crushing of cerebral tissue, degree and depth of infected wound, disturbance of circulation, resistance of patient, etc. Gas infection of the brain has several distinguishing signs and symptoms as compared with the similar infection of muscles—prolapse of cerebral tissue, bursting headache, meningitis, absence of crepitations (as in muscles).

Prof. Sacharov is carrying out experimental work on rats and mice infected with gas gangrene of the brain (Table IV). Infecting the animals with *Cl. perfringens* directly into the cerebral hemispheres beneath the dura mater without causing any trauma to the cerebral tissue, he was able to demonstrate that they died from acute cerebral oedema, cerebral softening, and other septic symptoms of gas infection.

Several cases of cerebral abscesses of anaerobic origin have been described: during the war of 1914-17 Academician Burdenko observed cerebral abscesses containing anaerobes. There has, however, been no research into gas infection of the brain complicating cerebro-cranial injuries. Military Surgeon Frantz gives statistics of 118 cases of gas oedema of the brain during the war of 1914-17; but his data are incomplete, as they do not include anything of clinical or bacteriological value.

Conclusion

Our experience proves that the best results in gas infection of the brain are obtained by active surgical intervention and the use of anti-gas-gangrene serum. We boldly dealt with the excision of prolapsed brain tissue, the gas infection, and the removal of necrotic tissue, applying sulphanilamide and sulphathiazole emulsion to the cavity. Orally we gave sulphanilamide 1 g. six times in 24 hours; and, intravenously, 1% solution of sulphathiazole 2 to 3 times daily in doses of 30 to 40 c.cm. in meningeal involvement, with 0.8 g. sulphanilamide intrathecally. We carefully watched the blood for any signs of agranulocytosis. Where this occurred we gave a blood transfusion and did not stop the active sulphonamide therapy. But very often in such a complication we reduced the sulphonamide dose, and in order to lessen the toxic effects on the blood transfused 250 to 350 c.cm. of blood, using anti-gas-gangrene serum at the same time. In our opinion it is imperative that instruction should be issued to all front-line dressing stations about the use of anti-gas-gangrene sera and local and oral sulphonamide therapy in contaminated penetrating cranial injuries, which are so often complicated by gas gangrene.

The Interdepartmental Committee on Dentistry, recently set up under the chairmanship of Lord Teviot by the Minister of Health and the Secretary of State for Scotland, has invited certain interested bodies, including associations of local authorities and dental associations, to submit evidence bearing on their terms of reference, which are as follows: To consider and report upon (*a*) the progressive stages by which, having regard to the number of practising dentists, provision for an adequate and satisfactory dental service should be made available for the population; (*b*) the measures to be taken to secure an adequate number of entrants to the dental profession; (*c*) existing legislation dealing with the practice of dentistry and the government of the dental profession; (*e*) measures for the encouragement and co-ordination of research into the causation, prevention, and treatment of dental diseases.

Medical Memoranda

Trophic Necrosis, Skin-grafting, and Vitamin C

During 20 years' practice I have seen 3 cases of scurvy, all within the last four years. There are now simple methods of estimating vitamin excretion in the urine applicable directly to ascorbic acid, thiamin hydrochloride, and nicotinic acid, and indirectly to vitamins A and D. Soon riboflavin is likely to join the former category. It is therefore possible to approach the subject of avitaminosis without dependence on theoretical and commercial claims, and to do so is to learn much of interest and value. This is illustrated by the two undermentioned cases of ulceration of the leg.

CASE I

A farmer's widow aged 69 complained of sores on the leg. Onset was acute, with much pain. She was of a thin hard-working type. Temperature 100°. Three areas of discoloration and apparently superficial ulceration on the right leg. Large varicose veins. Urine contained neither sugar nor albumin. W.R. was negative. Two days later the three ulcers had become circumscribed patches of black moist gangrene. She was removed to hospital. Fresh ulcers appeared, and she developed circumcorneal ulceration. There was no improvement until, on finding that the urine contained no ascorbic acid, 150 mg of ascorbic acid was given daily by the mouth. Skin-grafting of the two largest patches, 3 in. by 2 in., was successful, and progress was uninterrupted.

CASE II

A woman aged 70 has for 20 years had large superficial areas of ulceration of both legs, 4 in. by 6 in., and extending halfway round the limbs. There were no visible varicose veins. The skin generally was thin and white. Five years previously this patient was in hospital under my care. Routine treatment was without effect and skin-grafting completely failed.

She was readmitted on Aug. 2, 1942. No vitamin C (ascorbic acid) excreted in the urine. Course of ascorbic acid, 150 mg. daily, begun. First leg grafted Aug. 9 (Reverdin); second leg grafted Aug. 31. Discharged healed, and much improved in general health, on Oct. 21.

COMMENT

These two patients illustrate another aspect of avitaminosis which I cannot at present explain—namely, the considerable individual variation in vitamin C sub-saturation found in practice. Case I required 150 mg. daily for 8 weeks before ascorbic acid was excreted regularly in the urine. On two occasions increase of the daily dose to 700 mg. secured small urinary excretion (0.8 and 1.5 mg. per 100 c.cm. respectively). Although this patient had achlorhydria (as is the rule when the urinary execretion of ascorbic acid is *nil*) the administration of HCl apparently did not improve the absorption of the ascorbic acid. Case II, on the other hand, showed urinary excretion of 1 mg. per 100 c.cm. on the sixteenth day, and maintained this rate.

The analyses were made by Mr. R. O. Eames, F.I.C.

The conclusion reached is that vitamin C is indicated in some cases of trophic ulceration, especially before skin-grafting, and the amount for control by estimation of the urinary excretion.

Caernarvon. GRIFFITH EVANS, F.R.C.S.

The Diagnosis of Alkaptonuria

Alkaptonuria is a rare irregularity. The symptoms are slight dysuria and frequency of micturition at night. The condition is said to be due to an inborn error of metabolism of the tyrosine linkage in the process of protein metabolism, the end-product being 1 : 4-dihydroxyphenyl-acetic (homogentisic) acid, which is passed into the urine. Alkapton urine is normal in colour when freshly passed, but on exposure to air and light rapidly darkens from the surface downwards, ultimately assuming a dark-brown or black colour. Addition of alkali increases the rate of oxidation. It reduces cupric oxide and also silver nitrate solution (cold).

1 : 4-dihydroxyphenyl-acetic acid may be regarded as a derivative of hydroquinone (Fishberg, 1942). Therefore its presence can be detected in urine quite readily by first making the urine strongly alkaline with caustic soda or caustic potash. A drop of the urine so treated will, when placed upon regulation sensitized photographic paper, instantly turn the latter black. This colour change does not take place with the substances occurring normally in urine, or pathologically except with homogentisic acid. Thus the diagnosis of alkaptonuria may be made.

School of Medicine, Royal Colleges, Edinburgh.

Reviews

UROLOGY IN WAR

Urology in War. Wounds and Other Emergencies of the Genito-Urinary Organs, Surgical and Medical. By Charles Y. Bidgood, Lieut.-Commander, U.S.N.R., Chief Urologist, U.S. Naval Hospital, Washington. ($2.00 or 11s.) Baltimore: The Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1942.

This small handbook of 78 pages will be useful as a manual of reference to those engaged in the general surgery which war inevitably provides. In wartime high specialization is only a make-believe. Bombs and bullets do not respect anatomical limitation: the injuries are usually multiple and widespread. The scope of the book is made clear in a foreword by Rear-Admiral McIntire, Surgeon-General U.S. Navy. It is intended not necessarily for urologists but for surgeons who have to care for emergency conditions arising from wounds or disease of the genito-urinary tract. The surgeon on active service needs wide training in general surgery in order to fulfil his mission. He will welcome small volumes for his portable library such as that under review. If some wound of the genito-urinary tract calls for priority in treatment, he has at hand instructive information presented in attractive form. In an emergency he will gain rapid guidance from 27 descriptive and elegant illustrations.

Ruptured urethra is a comparatively common injury in war. The recommendations for treatment lack clarity and are too short. Fig. 10 illustrates the operation for anastomosis of the urethra described and illustrated by W. de C. Wheeler (*Proc. roy. Soc. Med.*, 1928-9, **22,** 469). Other sections give treatment in more detail and sometimes with an exactitude which leaves nothing to be desired. Some novel procedures are illustrated, such as the transfusion of blood into the corpus cavernosum, when the veins of the limbs are not available.

A SYNOPSIS OF TROPICAL MEDICINE

Synopsis of Tropical Medicine By Sir Philip Manson-Bahr, C.M.G., D.S.O., M.D., F.R.C.P. (Pp. 224; with 5 plates. 7s. 6d.) London: Cassell and Co., Ltd. 1943.

Those who are familiar with *Manson's Tropical Diseases* will not fail to recognize the close connexion it has with the *Synopsis of Tropical Medicine*—in fact, the latter, by the same author, is a synopsis of the former. As the larger book deals with nearly every aspect of tropical medicine, so also does the smaller synopsis, the difference being largely due to the suppression of all redundant matter. The result is that the synopsis gives essentially the same information as the larger book but in a form which is more that of a catalogue and which, in consequence, is perhaps more difficult to read. Nevertheless the *Synopsis of Tropical Medicine* is a veritable mine of information which for all practical purposes is remarkably accurate and cannot fail to supply the student with all that he may require for the practice of medicine in the Tropics. The size of the book is such that it will slip into the jacket pocket, so that we predict it will be the constant companion of the very many whose duty it is, particularly at the present time, to practise in a field of medicine which in ordinary circumstances would have been closed to them. The author is to be congratulated on his very successful contribution to the war effort.

OTO-RHINO-LARYNGOLOGY IN THE SERVICES

The Ear, Nose and Throat in the Services By R. Scott Stevenson, M.D., F.R.C.S.Ed., Major, R.A.M.C. Oxford War Manuals. (Pp. 116 5s.) London: Oxford University Press 1943

The nature of the author's own service naturally makes him most familiar with practice in the Army, but he has designed his book to meet the needs of the Navy and the R.A.F. also. It will, however, be most useful to officers of the R.A.M.C. whose lot it is to deal with large numbers of minor maladies, especially of the ears, and a few serious cases. The author has put his knowledge and experience to good use in compiling this little manual, which is of necessity superficial, but in spite of its modest size contains a great quantity of information of the kind likely to be required. It recalls a similar book in French by Bourgeois and Sourdille which was most useful during the war of 1914-18, but since that time the electric otoscope, chemotherapy, and audiometry, besides other improvements, have come into general use, so that there is need for a modern book of the same type. The aim of practice in the R.A.M.C. is naturally to keep men fit for service, and if they need treatment to provide such treatment that the period of absence is as short as possible, the clinical material being drawn from a highly selected group of the population. Yet in spite of this process of selection the type of case which presents itself, having regard to the limitations of sex and age, differs but little from that encountered daily in departments for out-patients, and gross malingerers are quite uncommon—certainly much less common than the numerous neurotics who infest the civilian out-patient clinics to-day in their efforts to avoid some form of national service. This is an aspect of practice which total war has made almost universal. The author approaches with excellent sense the question of excising the tonsils in soldiers. It is an operation which is easily abused and is naturally rather discouraged, but where it is evident from the history that recurrent attacks of tonsillitis are making a man unfit and repeatedly absent, the man can easily be made fit and his health improved. If junior officers of the R.A.M.C. will read the book they will have reason to be grateful to Major Scott Stevenson for his guidance.

PAEDIATRICS

Advances in Pediatrics. Volume I. Editor, Adolph G. De Sanctis, M.D. (Pp. 306. 21s.) London: William Heinemann.

The 1942 Year Book of Pediatrics Edited by Isaac A. Abt, M.D., with the collaboration of Arthur F. Abt, M.D. (Pp. 512; illustrated. 19s.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co. 1943.

It is argued that the days of the textbook in medicine are past, for progress is too rapid, and large volumes taking a long while in preparation get out of date by the time of publication. There is certainly a lot to be said for this, especially in the postgraduate field, and the first volume of a new series entitled *Advances in Pediatrics*, edited by Dr. A. G. De Sanctis and consisting of a series of monographs, represents the new type of publication. Eleven authors have taken part, producing nine monographs and a final chapter on recent advances of a more miscellaneous type. Selection was guided by a questionary sent to the leading paediatricians in the United States, and the following are the titles of the subjects chosen as having shown important changes in the past two years: toxoplasmosis, virus diseases, chemotherapy, electro-encephalography, vitamin K, surgical treatment of persistent ductus arteriosus, prematurity, tuberculosis, endocrinology. Of these, the first can be mentioned for its novel character, the disease discussed being quite unknown in Great Britain; and for special merit Dr. Waldo E. Nelson's contribution on tuberculosis can be rightly singled out, although the whole standard is remarkably high.

In *The Year Book of Pediatrics* Profs. I. A. Abt and A. F. Abt continue their extremely able annual review of the literature, mainly American, in this field. As usual, the editorial comments form an important part of the book's value, and an excellent index makes it easy to use the volume as a work of reference. Among British authors cited it is a pleasure to see appreciation of Prof. C. McNeil's advocacy of infant hygiene and breast-feeding, and there are also various references to articles which have appeared in the *Archives of Disease in Childhood*. The illustrations are well chosen, and the standard of reproduction indicates that American editors and publishers have not yet had to grapple with paper shortage.

Notes on Books

In 1941 Mr. WILLIAM MAIR compiled *An Index of New Remedies* containing a list of recently introduced drugs, etc., with short notes on the therapeutic purposes for which they were recommended. In view of the desire of manufacturing firms to label their products with names registered as trade marks, and the hindrance that this is to the development of any rational nomenclature for new drugs, Mr. Mair's pamphlet provided a very useful work of reference. Its cordial reception in these columns and elsewhere has led to the preparation of a second series, *An Index of Modern Remedies*, which is published by the *Scottish Chemist* for the medical and pharmaceutical professions from 240, Albert Drive, Pollokshields, Glasgow, at the price of 1s. 6d. Like the first, it is essentially an index. Information on any given item may be readily found by means of the alphabetical list at the end of the pamphlet.

The Metabolism of Fat, by IDA SMEDLEY-MACLEAN, D.Sc., of the biochemical department of the Lister Institute of Preventive Medicine, is a recent addition to Methuen's Monographs on Biological Subjects (price 5s.). It is an attempt to give in very brief compass a critical account of some of the more important developments in our knowledge of the metabolism of the fatty acids—a problem now being attacked by more and more investigators from widely different points of approach. For her present purpose the author has picked out what seemed to be the most significant results and has endeavoured to piece them together. The bibliography grouped under the several chapters will give useful pointers to those wishing to amplify this introduction to the subject by reference to contemporary periodical literature.

Preparations and Appliances

A PORTABLE SUCTION APPARATUS NOT DEPENDENT ON A SOURCE OF ELECTRICITY

N. F. SAHER, M.B., D.A., and R. SALT send the following description from the Nuffield Department of Anaesthetics, University of Oxford.

In the apparatus described here a cylinder of compressed gas, such as oxygen, is used as a source of energy. The gas is fed to an ejector unit and produces suction at any negative pressure up to a maximum of about 400 mm. Hg. When a cylinder containing 20 c.ft. of oxygen is used and the negative pressure is adjusted to 200 mm. Hg continuous suction can be obtained for about 40 minutes. Previously, suction apparatus working on the ejector principle was described by Mr. Norman Lake (1924). In his apparatus, however, the gas was fed direct from the cylinder to the jet of the ejector unit. While that arrangement was effective it was rather wasteful in gas, especially as the suction became practically ineffective as soon as the pressure in the cylinder fell below 30 atmospheres, which resulted in about a quarter of the contents of each cylinder being wasted. The apparatus now to be described is more efficient, and therefore more economical in gas: practically the whole contents of each cylinder can be used. Moreover, the negative pressure is easily adjustable.

The apparatus is built up on a stand, with castors, intended for an oxygen cylinder of either the 20-c.ft. or the 40-c.ft. size. To the cylinder is fitted a reducing valve (Fig. 1, A)—e.g., McKesson or similar type—having a tyre-clip adapter to which high-pressure tubing is attached. Through the tubing the gas is led to a Schraeder stop-valve (Fig. 1, C, and Fig. 2). This valve is placed in a convenient position to enable the oxygen flow to be switched on or off by foot control, which helps to economize in oxygen. When the foot button is pushed down, oxygen passes into the ejector system and produces a negative pressure at the entrainment port (Fig. 1, D, and Fig. 2). If the ejector is fitted with a No. 70 Amal jet it has been found possible to obtain any required negative pressure within the range mentioned simply by adjustment of the reducing valve, and at the same time to preserve a reasonable economy in oxygen consumption. A reduced-pressure gauge calibrated in mm. Hg (Fig 1, B) is provided on the low-pressure side, and indicates the negative pressure obtainable at various settings of the reducing valve. The outlet of the ejector system is fitted with a silencer (see Fig. 2). When the foot button is released the oxygen flow is stopped.

The entrainment port (Fig. 1, D) is connected by tubing to a glass bottle (Fig. 1, E), which is in a cage fixed to the cylinder stand. A second tube leads from the operation field. There, aspiration can be carried out with any of the various catheters or suction tips in common use. The aspirated material collects in the glass bottle.

Performance of the Apparatus

(*a*) *With the Reducing Valve set to 24 lb. per sq. in.*—The rate of oxygen usage is 12.5 litres per minute (measured at atmospheric pressure). When the suction side of the apparatus is closed to prevent entry of gas or liquid the negative pressure produced is 200 mm. Hg. As is to be expected, the time taken to attain this negative pressure depends upon the volume of air in the suction side of the system, mainly in the collecting bottle, before the oxygen flow is started, and upon the resistance of the tube connecting the ejector unit and the collecting bottle. This latter consists of two feet of thick-walled rubber tubing of 1/4 in. internal diameter. With an empty three-pint bottle the full negative pressure is attained in 11 seconds; with a one-pint bottle, in seven seconds. The rate at which the apparatus sucks up water through a Magill No. 0 tube, attached to the collecting bottle by a metal connector and four feet of thick-walled rubber tube of 1/4 in. internal diameter, is 1,200 c.cm. per minute. The rate at which the apparatus sucks up blood is about 1,020 c.cm. per minute. These figures give some idea of the capacity of the apparatus in the conditions stated. Naturally, the volume sucked per minute will be smaller if a fluid more viscous than blood is being dealt with. Moreover, if a longer tube is substituted for the Magill No. 0 or a tube of smaller bore is used, the resistance to the passage of fluid is higher and consequently the volume sucked per minute will be lower.

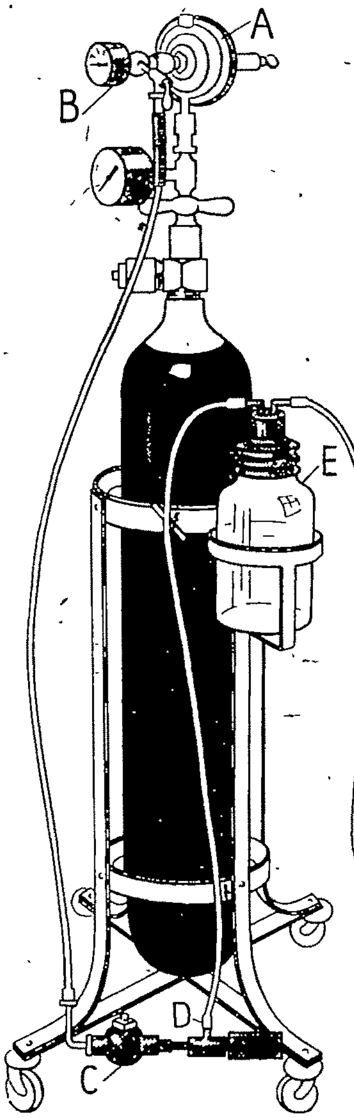

FIG. 1

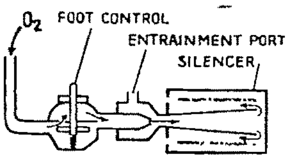

FIG. 2

As might be expected from the figures already given, the time lag between starting the oxygen flow and the beginning of suction flow is influenced by the size of the collecting bottle if empty, or the volume of the air space in the bottle if partly full. With a one-pint bottle the time lag before visible suction of water begins is about one second; with a three-pint bottle the lag is about 2½ seconds.

(*b*) *With the Reducing Valve set to 35 lb. per sq. in.*—The rate of oxygen usage is 15.5 litres per minute. The negative pressure produced when the suction side of the apparatus is closed is about 300 mm. Hg. Therefore a cylinder containing 20 c.ft. of oxygen provides continuous suction for about 30 minutes. The time taken to attain the full negative pressure of 300 mm. Hg is 15 seconds when an empty three-pint collecting bottle is used, and 11 seconds with a one-pint collecting bottle. Although there is a time lag before full negative pressure is reached, actual "entrainment" of water begins almost at once. The rate at which the apparatus aspirates water in the conditions stated above is 1,300 c.cm. per minute; for blood the rate is about 1,040 c.cm.

This apparatus can be obtained from Medical and Industrial Equipment Ltd. of 12, New Cavendish Street, London.

FOURTH CENTENARY OF "DE FABRICA"

This year marks the four-hundredth anniversary of an event of the highest significance for our civilization—the advent of the modern view of the material world. The universe of medieval thought was very different. In its centre lay the "corruptible" spherical earth. Round it circled in order the "incorruptible" heavenly bodies, each in its proper sphere and each sphere within the next, like skins of an onion. The influence of these bodies entered all earthly activity, disposing, if not forcing, even the human will. Hence the universal respect for astrology, which was a theory as to how the parts of Creation were related to each other. The world had been made for man, and it was natural to believe that his bodily organs were related to this plan, certain planets or constellations affecting certain organs. Thus arose elaborate schemes of the relation of the "Macrocosm"—the great outer celestial world—to the "Microcosm"—the little inner world of man himself.

In May, 1543, the aged Polish astronomer, Copernicus (1473-1543), lay on his death-bed and a copy of his book *On the Revolutions of the Celestial Spheres* was rushed to him. As all know, it sets the sun in the centre of the world and the earth, like other planets, moving round it, the whole system being bounded by an outermost starry firmament. This system was incompatible with medieval astrology and in that sense was revolutionary. Yet, despite the great battle that came to be fought in the name of Copernicus, it is not really a modern book in the proper sense. Its tone is still scholastic. It contains few observations. By retaining the system of regular movement in circles and the fixity of the firmament it proclaims its medieval roots. It is a work of ratiocination in the medieval manner. Utterly different was the other great scientific book of 1543, nor could two men be more contrasted than the Pole Copernicus and the Belgian Andreas Vesalius (1514-64), whose work is described on another page by Dr. E. Ashworth Underwood.

Vesalius studied at the Universities of Louvain and Paris. In both the teaching of anatomy was quite medieval in method and substance. The professor lectured always from his Chair, a physical reality in those days—a great pulpit with a reading desk. There he read from the text of Galen—hence the academic title "Reader"—commenting on it as he went, while his "Demonstrator" directed with his wand a menial to the actual task of dissection. All was done third-hand and according to the written word. Vesalius soon revolted against this system and betook himself to Padua, long renowned as a medical centre. By his work there he succeeded in a surprisingly short time in changing completely the whole content and tradition of thought about the human body, and indeed of thought about the universe as a whole. From his time we may date the establishment of anatomy as the positive basis of medical teaching. Vesalius was still only 28 when, in June, 1543, there was issued at Basle his *De humani corporis fabrica*. With this great book the scientific study of living things began again where Aristotle and Galen had left it in antiquity. The personality of Vesalius impressed itself on the whole conception of the human *fabrica*—a word which had, for him, the sense of something at work. It was always living anatomy that he was trying to describe, and, as a corollary, it was always the body as a whole that was in his mind. This vision of the living *fabrica* made him a great creative anatomist, but it made him at the same time a creative artist. Yet this vision makes his work difficult reading for us, since to understand it we must rid ourselves of certain ideas that we accept automatically and unconsciously. The modern biologist deals with descriptions and origins. He takes an organ or part or function or reaction or group of organisms, and investigates it in detail. Then he treats it comparatively and considers its relation and descent. His thought is always saturated with evolutionary implications. But with Vesalius it is not so. For him the body is a piece of living workmanship made by the Great Craftsman. The parts must be considered always in relation to the scheme as a whole, and treated as contributing to that complex that we call a man. Thus, for example, his famous general figures of bones or of muscles are not diagrammatically displayed from front, back, and side, as in a modern treatise, but posed as in the living body. They are given tone and movement and provided with a background such as they would have in life. This method is used with all the artist's skill. It was his own; nor need we discuss the share that any other artist, Calcar or another, had in the drafts, for the artist's mind that conceived them was that of Vesalius.

Vesalius was trebly equipped for his task: first, by a wonderful native genius for anatomical observation and classification; second, by great powers of imagination exalted by contact with high models of Renaissance art; third, by an admirable education directed along humanist lines by some of the ablest humanists of the day. But he was also most happily constituted for his task by the *lack* of certain qualities which would have handicapped him in that age. Philosophical or theological problems were far from him. He was not at all given to the drawing of those vague physical analogies typical of the men of his time, who borrowed much of this sort from Aristotle. From diversion into the miraculous or magical he was saved by a mind stocked with what he actually saw and did. Vesalius was a thorough extrovert; of stable, unsubtle, constructive, yet restless mind; with an artist's eyes, hands, and imagination: the very type and exemplar of the modern man of science. The work of Vesalius is thus great in a very different sense from that of Copernicus. The *De revolutionibus orbium celestium* is a foundation work of modern astronomy and displaced the medieval view of the Macrocosm, but it is a feat of ratiocination rather than observation. The *De humani corporis fabrica* is a foundation work of modern biology and displaced the medieval view of the Microcosm, but its vast treasury of direct observation is set forth in a systematic and orderly fashion and in the full modern manner. If one took certain parts of it, correcting a few errors, it would read like a series of articles in a modern scientific journal. Thus it is fair to claim that it is not only a foundation work of modern science but also the first modern scientific book. In this additional sense it opens the modern period of science.

TUBERCULOUS EMPYEMA

Tuberculous empyema is only too familiar to those undertaking the treatment of pulmonary tuberculosis. Any contribution to the prevention and treatment of this unfortunate complication, in terms of general principles or of technical details, is to be welcomed. We are glad, therefore, that three opening papers read at a recent meeting of the Tuberculosis Association are now in print.[1] The preventive treatment of the condition, especially as it occurs during artificial pneumothorax, was stressed by Dr. C. Hoyle. A pneumothorax is often maintained when adhesions are preventing proper collapse of the diseased areas of the lung, and the incidence of empyema is high in this type of case. Unless the restricting adhesions can be divided by cauterization, the pneumothorax should, as a rule, be abandoned. Once an empyema has developed, a primary consideration is the presence or absence of a secondary pyogenic infection. Only very rarely may a secondary infection die out or be overcome by local and general chemotherapy; but no reliance should be placed on this. The correct procedure is to secure proper surgical drainage at once and, whenever possible, to proceed to an early thoracoplasty.

While there is fairly general agreement on this, there is greater difference of opinion on what should be done for the simple forms. All the speakers were agreed that the best possible treatment is to obliterate the infected pleural space by inducing expansion of the lung by aspiration and pleural lavage, preferably with an antiseptic. Unfortunately this happy result is achieved in only a small percentage of cases. Either the lung will not expand completely or the presence of uncontrolled active disease in it makes this undesirable. If the pulmonary condition does not demand permanent collapse it is proper to give a trial of aspiration and lavage. Dr. W. C. Fowler made some useful practical observations on this. He laid down that every case should be treated from the start with the idea that a thoracoplasty may be needed sooner or later. Punctures for lavage should therefore be made well away from the possible operative field, and preferably high up in front of the chest wall above the level of the fluid. With the aid of a thoracoscopic trocar and cannula, a rubber catheter or a suction tube can be passed down to the bottom of the pleural space and masses of debris which would never pass through an ordinary needle can be sucked out. A thoracoscope may also be inserted for inspection of the cavity. A puncture made high up in this way heals safely and quickly, unlike the usual puncture made at a low level, which is expected to heal in a bath of residual tuberculous pus. The development of tuberculous sinuses, often with extensive infection and cold abscesses of the chest wall, is a grave complication of an already serious condition, and if Dr. Fowler's technique were followed many of these distressing results would be prevented.

Opinion is sharply divided between the need for radical treatment and the continuance of conservative treatment in those cases that do not respond to simple aspiration and lavage. Oleothorax has but few supporters. The late Dr. Chandler[2] made a plea for recognizing that in a small proportion of cases a purulent collection may become encysted and harmless, or even beneficial, as a sterile plomb. While this may sometimes occur, it is unsafe to rely upon it; and it is very difficult, if not impossible, to pick those cases which might be expected to follow such a benign course. Continued conservative measures, especially in the presence of disease of the underlying lung, expose the patient to the risk of the grave complications of rupture into the lung and of secondary infection. Mr. R. C. Brock quoted figures from the literature and from his own series in favour of early thoracoplasty when conservative measures have failed. Woodruff,[3] reporting on 154 cases of tuberculous empyema from Saranac Lake, had found that "of those patients who originally had a non-contaminated tuberculous empyema and who did not die of it, 30% finally developed complications either by perforation or by secondary infection." Of the 154 patients 64 were known to be dead at the time of the follow-up, a mortality of 42%. In Mr. Brock's series conservative treatment yielded very poor results, the mortality being 44%, almost the same as in Woodruff's series. In the secondarily infected group the mortality in patients not strong enough to undergo thoracoplasty was over 90%. Thoracoplasty gave very good results in simple tuberculous empyema, there being only one death in 21 patients. In the secondarily infected group the mortality of thoracoplasty was 29%; sound healing was achieved in 15 out of the 35 survivors.

It is clear that thoracoplasty combined with drainage is the only thing that holds out hope to the patient with a secondarily infected tuberculous empyema. The problem is more difficult in the uncontaminated case. The advocates of conservative measures point to their few successful cases, perhaps forgetting those which have progressed to fistula, secondary infection, and death. Those who advocate radical treatment by thoracoplasty consider the results to be so much better, and the mortality so much lower, that such treatment is clearly indicated whenever conservative treatment has failed after a fair trial.

PARATYPHOID FEVER

It is becoming increasingly evident that paratyphoid fever exhibits many differences from typhoid fever in its epidemiological features, as Sir William Savage[4] has shown in a study of forty outbreaks in Great Britain due to *Bact. paratyphosum* B. The incubation period is variable and, in general, shorter than it is in typhoid. As well as being a milder disease, the case mortality in paratyphoid is lower, approximating to the case mortality of *Salmonella* food-poisoning. Although characterized by an insidious onset, a proportion of attacks are initiated by acute gastro-intestinal symptoms simulating acute food-poisoning. As in typhoid, the portal of entry of the paratyphoid bacteria is through the intestinal lymphatics, and during the incubation period they multiply in the liver, spleen, and mesenteric lymph glands. A bacteriaemia initiates the onset of symptoms, and excretion of the organisms soon follows into the intestine via the bile. Contrary to the older conception, it is considered that Peyer's patches are then invaded, because it has been shown that the intestinal mucous membrane is in itself an efficient barrier against direct bacterial invasion. There is a tendency to a summer prevalence of paratyphoid outbreaks comparable with the seasonal incidence of *Salmonella* food-poisoning. Infected foodstuffs were responsible for 80% of the forty outbreaks, and half of these were traced to cream or cream cakes. Water was rarely a vehicle, and shellfish were not once implicated. Search of the literature reveals very few outbreaks of paratyphoid B fever that could be proved conclusively as water-borne. There was the Brixworth outbreak mentioned in Sir William's series, with only four cases, and Hippe described a small outbreak on a farm in Schleswig-Holstein. There was gross and continued pollution of the water with sewage in both instances. Paratyphoid bacteria survive in sewage and sewage effluents for a considerable time. That infection has been traced to cream is interesting, for it is probably a good medium for growth when the temperature is fairly high; but more information is required on this point. Cream is a vehicle that affords ideal opportunities for infection from a specifically infected food handler, and although cream, particularly the artificial kind, is manufactured by but a few firms, it is distributed over a wide area before it is further processed and introduced into cakes and pastries.

[4] *J. Hyg.*, Camb., 1942, 42, 393.

There is no doubt that the number of notified cases of paratyphoid fever forms only a small proportion of the total infected. There are many mild undiagnosed cases, and examination of more than one outbreak has revealed many infected persons without symptoms. The most frequent sources of infection are the ambulatory unrecognized case and the bacterially infected person without symptoms, rather than the chronic carrier, who is the usual source of infection in typhoid fever. A proportion of cases remain as temporary carriers, but we do not know the percentage of patients who become chronic—that is to say, who continue to excrete the organisms for more than a year after convalescence. Paratyphoid B bacteria have, however, been isolated from crude sewage and unchlorinated effluent at Epping for nearly ten years after the outbreak of 1931. Apart from 22 cases in 1933 traced to infection of cows' udders with sewage, no abnormal notification of cases has occurred in this locality in spite of the persistence of this reservoir of infection. When searching for the source of infection, close attention must be paid to dates and past and clinical history of the suspected carrier. The agglutination test is of considerable value, and O, H, and Vi agglutinins should be separately estimated; consistently low titres are of considerable significance. *Bact. paratyphosum* B is generally considered a human parasite, but there is evidence recently from Scandinavia that dogs may become infected. Sir William Savage explains the differences in the epidemiology of paratyphoid and typhoid fevers by considering *Bact. paratyphosum* B as a true *Salmonella* in an evolutionary stage. This organism must be present in large numbers for a successful invasion of the tissues; thus, water-borne infections are rare unless the contamination is massive, while vehicles in which the organism is able to multiply are frequent causes of outbreaks.

TOXIC PROPERTIES OF INDIUM

Indium is a silver-like ductile metal, untarnishable by air and unaffected by water, which, owing to its substitution for other less readily available metals, now finds increasing use in industry for plating by electrodeposition. Its three best-known compounds are the trichloride ($InCl_3$), the sulphate ($In_2(SO_4)_3/9H_2O$), and the sesquioxide (In_2O_3). The last is used chiefly in glass manufacture, while indium cyanide is also used as a plating solution. Therapeutically, indium has been tried in the treatment of trypanosomal and spirochaetal infections. Earlier animal experiments have established the fact that indium is indubitably toxic and have indicated the nature and site of its toxic action. The lethal dose of indium citrate by subcutaneous injection was found to range from 0.06 g. per kg. body weight for mice to 2 g. per kg. for rabbits, and by oral administration from 1.2 g. per kg. for rats to 2 g. for rabbits. Death from asphyxia was preceded by hind-leg paresis, rapid and spasmodic respiration, and convulsions. Some indication was given by these experiments that indium, like thallium, had a depilatory action. A more recent investigation[1] has attempted a closer approximation to conditions of industrial exposure to indium, and has included an examination of its possible effect as a skin irritant on both animals and human beings. The results of application of indium cyanide to the shaved skin of animals are particularly interesting, because indium cyanide represents the chief indium risk in industry. Local caustic action was followed by rapid death, but control experiments with sodium cyanide showed that this severe toxic action could not be attributed to indium, but rather to the cyanide component, as the same effect was obtained with equal amounts of sodium cyanide, and no such injury followed the application of indium chloride or sulphate or of metallic indium. Subcutaneous injection of indium sulphate and chloride in amounts varying from 2 to 6 mg. per kg. body weight caused, especially in rabbits, rapid anorexia and loss of weight, followed by nose bleeding, paresis of the hind legs, and twitching of the muscles—a picture similar to that of a mild degree of strychnine poisoning. Intravenous injection was followed by the same syndrome, but with a relative toxicity about four times that of subcutaneous injection. Post-mortem examination revealed widespread haemorrhage in the lungs, liver, kidneys, and ureters; inflammatory changes in the liver, kidneys, and heart; and atony of the gastro-intestinal tract and urinary bladder. The liver was the organ most severely affected. Albumin and indium were present in the urine. Blood counts, where these could be made, showed in general less severe damage than had previously been believed to occur, but there was a trend towards diminution of red cells and haemoglobin, haemolysis, and the appearance of nucleated red cells. In human beings no evidence of any skin-irritant property of indium resulted from the wearing on the forearm, for periods up to 30 days, of indium-treated silver plates. Incidentally, these experiments showed that indium diffused into silver has no anti-tarnishing effect. The depilatory action of indium mentioned in earlier experiments was not confirmed by the application of indium salts to the hairy coat of animals. From this investigation it appears that, while indium has undoubtedly toxic properties, its industrial application does not constitute a toxic hazard, even as a skin irritant.

HEALTH PROBLEMS IN THE NEW LONDON

London will be in the hands of the builder for many a long year after the war, and in a recent Chadwick lecture Dr. C. F. White, medical officer of health for the City, addressed himself to some of the health problems that will rise up with the post-war scaffolding. In spite of extensive destruction in certain areas, the London of the future will not differ very much in lay-out from the London as we have known it. Some sites which have been cleared, it is to be hoped, will not be built on; some thoroughfares will be widened, but the centre of London will bear much the same contours as before; and, although business and pleasure may be rather more decentralized, there will still be the enormous centripetal flow of population every morning. Dr. White foresees some decentralization of hospitals, but he is of opinion that the teaching hospitals and their medical schools must remain in central London, near the University. One would not have supposed that, with modern transport, this consideration carried its former weight, and indeed for many years one of the teaching hospitals (King's College) has been situated three miles or more from Charing Cross. Dr. White spoke of the need for flat roofs as open spaces and the allocation of basements for the purposes of machinery and stores only. The sterilization of air by sprays and vapours, the control of air-borne infections in offices, and structural rat-proofing, which in his view is the only rat-repressive measure of permanent value, are all matters to be considered in the rebuilding of business London. But until the architects have got further on with their plans the medical officer of health cannot be very specific. Dr. White also touched on future London government. What kind of local authority can best manage London? It must not be so small that it cannot provide an efficient service, nor so large that the personal touch essential to successful administration is lost. Many present units of local government in London are too small; on the other hand, Dr. White thinks the county council is too large. It is true that the population of the county of London is more than sixfold that of the administrative county of Lancashire and nearly threefold that of the West Riding of Yorkshire. On the other hand, is density of population the determining factor? In area the West Riding could contain twenty Londons, and Lancashire fifteen. Moreover, the area of the London County Council, large as it is, is compact; it is a cartwheel structure. If the L.C.C. is too big as a unit of local government, how shall London be divided? To bisect it by the Thames, as it is geographically bisected, would be likely to introduce more complications than it solved. The problem which might well exercise the planners is not how London can be made smaller but whether it should not be enlarged by bringing in the boroughs and counties on its periphery.

[1] *J. industr. Hyg.*, 1942, **24**, 243.

PHYTIC ACID AND MINERAL METABOLISM

The rachitogenic property of cereals was first demonstrated by Sir Edward Mellanby by means of experiments on dogs. The agent responsible for this property was destroyed on boiling the cereals with 1% hydrochloric acid or by allowing them to germinate. Steenbock, Black, and Thomas[1] suggested that the phosphorus in the cereals was in an unavailable form, and that on treatment with hydrochloric acid or on the germination of the seed the organic phosphorus was converted into some more readily available inorganic form. Bruce and Callow[2] identified the organic form as inositol hexaphosphoric acid (phytic acid). Harrison and Mellanby,[3] working with dogs, found that the action of phytic acid was not only negative in that its phosphorus was unavailable to the animal but that it was positively detrimental in that it combined with the calcium of the cereal and of any other food eaten at the same time, forming an insoluble phytate and thereby removing the calcium from the food tract also. Indeed it was only after supplying enough calcium to combine with all the phytic acid present that additional amounts were available for calcification.

McCance and Widdowson[4] observed that healthy men and women absorbed calcium and magnesium much less readily from brown than from white bread dietaries, and showed that the effects of brown bread could be reproduced by adding sodium phytate to white bread. It was recognized, however, that the laxative action of brown bread might have exerted some influence on the absorption of calcium, and experiments were then carried out with brown bread from which the phytic acid had been removed.[5] They compared (*a*) a "brown" flour reconstituted from white flour and bran; (*b*) a flour mixture similar to the last but with the phytates hydrolysed enzymically to inorganic phosphates and inositol; (*c*) a mixture of white flour and bran from which nearly all the phytates and most of the products of hydrolysis had been removed; and (*d*) white flour. Each of 6 subjects (3 men and 3 women) were submitted to each of the above dietaries for periods of 7 days each for analytical work, with 3 days of preliminary feeding and several days of after-feeding on each diet. The orders of feeding were suitably "randomized." Calcium, magnesium, and phosphorus absorptions were studied. It was found that the laxative properties of the dietaries (*a*), (*b*), and (*c*) were approximately the same; that the calcium absorptions were worse in (*a*) than (*b*) and in (*b*) than (*c*), but almost the same in (*c*) and (*d*); that the magnesium absorptions improved progressively in passing from (*a*) to (*d*); and that the phosphorus absorptions were worse in (*a*) than (*b*) or (*c*) and a little worse in (*b*) or (*c*) than in (*d*).

Thus Mellanby's work on puppies has been extended to human beings and the same results obtained. The addition of calcium to brown bread would counteract its only known disadvantageous property and make it unquestionably superior to white bread in all known respects.

ROYAL MEDICAL BENEVOLENT FUND

For the first time for many years Sir Thomas Barlow, now in his ninety-eighth year, was absent from the annual general meeting of the Royal Medical Benevolent Fund. His place was taken by Sir Arnold Lawson, who expressed the general regret at his absence and the affection which is universally felt for him. The annual report of the Fund, presented by Dr. Lewis G. Glover, the honorary treasurer, showed a slight increase both in the subscription and the investment income. The Fund has been materially helped during the year by legacies amounting to £7,412, including a sum of £1,200 allocated by the British Medical Association as part of the bequest of the late Dr. T. C. Craig of Torquay. During the year the sum of £21,893 has been distributed in charitable assistance. The amount expended on gifts to beneficiaries, chiefly for maintenance, was just over £15,000, and on annuities £6,000. A sum of £1,277 was spent on social services and administration, and £644 on appeals and publicity. A pension scheme has been started for the staff of the Fund, with a commencing reserve of £2,000. The president, Sir Thomas Barlow, the honorary treasurer, Dr. Lewis Glover, and the honorary secretary, Mr. R. M. Handfield-Jones, were re-elected.

At the beginning of this month a number of men and women, lay and medical, Spanish, Catalan, Basque, and British, sat down to a dinner given in honour of Dr. Josep Trueta on the invitation of Señor Ramon Pereira, the President of the Casal Catala. The occasion was to celebrate the conferment on Dr. Trueta of an honorary D.Sc. of Oxford University. In response to Señor Pereira's speech of welcome, Dr. Trueta charmed his audience, in a reply mostly in English but partly in Catalan and Spanish, with a modest account of his own researches and a pleasant analogy between his technique of treating open wounds and the methods necessary to deal with political evils. In so far as there was any merit in his work, he said, tribute should be paid not to him but to Nature, whose methods of healing he tried to follow.

THE "FABRICA" OF ANDREAS VESALIUS

A QUATERCENTENARY TRIBUTE

BY

E. ASHWORTH UNDERWOOD, M.D.
Hon. Secretary, Section of the History of Medicine, Royal Society of Medicine

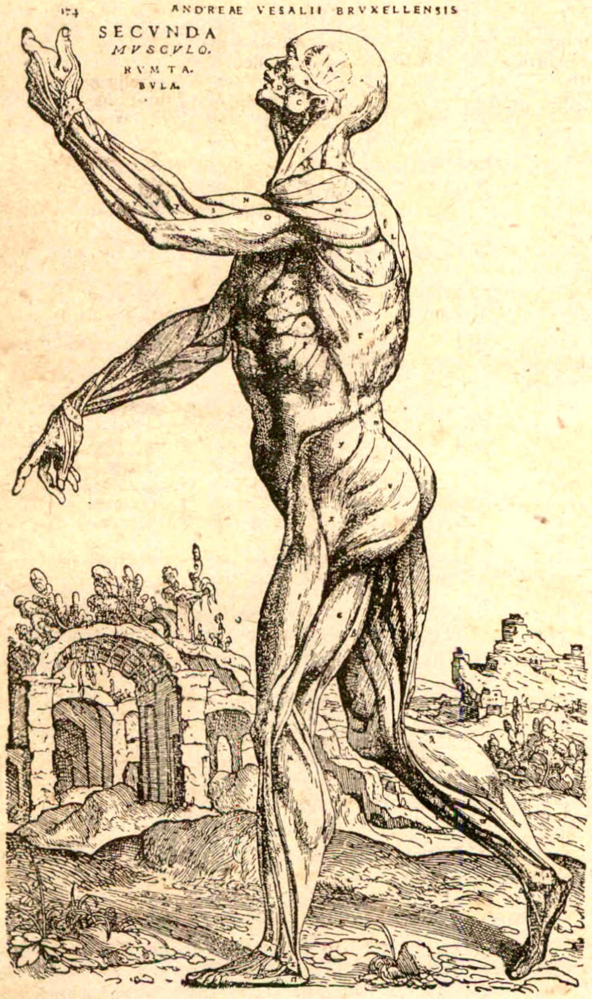
The month of June, 1943, marks the four-hundredth anniversary of the publication of one of the epoch-making works in all medical literature. Some time in the month of June, 1543, there appeared from the press of Joannes Oporinus, Professor of Greek at Basle, the *De Humani Corporis Fabrica* of Andreas Vesalius. It behoves us at this time to cast our minds back through the centuries, and to view in the light of later discoveries the work of this ardent reformer of anatomy and pioneer of the scientific spirit.

Vesalius was born in Brussels on Dec. 31, 1514. The son and descendant of court physicians and apothecaries, he received the thorough classical education of the age, studied medicine at Montpellier and Paris, and then settled for a time at Louvain. In these schools the trammels of the Middle Ages had not yet been broken by the spirit of the Renaissance. Anatomy was taught according to the views of Galen ; and, indeed, apart from the work of Mundinus two centuries before, and by then largely forgotten, there had been practically no development in anatomical thought throughout the Middle Ages. Mundinus published in 1316 a short work—in Latin of course—called *Anathomia.* Roth, the biographer of Vesalius, considers that it is well arranged and rich in "positive" anatomy. The terminology of Mundinus was derived mainly from the old Arabian writers. As an anatomist he had the virtue of carrying out his dissections in person, but as the years passed the professors who succeeded him undertook less and less of the practical work. An Italian translation of the *Anathomia*—the *Fasciculo di Medicina*—was published in 1493, and a remarkable illustration in that book shows the method of teaching anatomy two decades before the birth of Vesalius. The duty of the professor was to comment from the altitude of his "chair" on the writings of Galen, while his assistants below him dissected the body. Students never handled the subject at all. From his childhood Vesalius had had an urge for the dissection of all sorts of animals, and with such a system of teaching he could make little headway in the study of human anatomy. Subjects for dissection were difficult to obtain, and he has left an account of one of his expeditions to steal a corpse from a gibbet. Vesalius was attracted by the new learning of Northern Italy, and in 1537 we find him at Venice, where he was in the schools with Ignatius Loyola. While he was studying there he tells us that he treated patients, "not without the greatest expectation," by the new method of the China root. When he was 23 years old he graduated in medicine at Padua, and on Dec. 6, 1537, he was appointed professor of surgery, with the direction of a school of anatomy, at that university.

The next five years were pregnant for the future of medicine. At Venice Vesalius had met a compatriot, an artist, Jan Stephan van Calcar—*insignis nostri seculi pictor,* as Vesalius calls him—and in 1538 the two men collaborated in the production of six anatomical diagrams. Such "fugitive sheets" had been not uncommon in previous years, but those of Vesalius were anatomically and artistically a marked advance on their predecessors. Although they were extensively printed and pirated, all but two bound sets seem to have disappeared. They were reprinted in facsimile—thirty copies only—by Sir William Stirling-Maxwell in 1874, and in 1920 Holl and Sudhoff reproduced them by the photostat process. Vesalius was in 1538 still largely influenced by Galen. In fact in that year he edited a revised version of the *Institutiones anatomicae* of Guinterius, a pronounced Galenist and a former teacher of Vesalius at Paris. (Five years later he will tell us in the *Fabrica* that he is able to demonstrate more than two hundred errors of Galen.) He was, however, already famous, and he had evolved the modern or Vesalian method of studying and teaching anatomy.

The 1543 edition of the *Fabrica,* apart from its superb detailed descriptions of the "fabric" of the human body, contains three features—the Portrait, the Tabulae, and the Title-page—which are of vital interest in connexion with Vesalius himself and his method. The Portrait (see Fig.) was drawn by Calcar—

as were all the other illustrations in this magnificent book. It has long been considered to be one of the finest woodcuts of its age. The head is essentially Flemish in type, and the firm thick-set lips and piercing eyes seem to throw out a challenge to the world. The dissection chosen and the text of the scroll combine to exhibit the confidence of Vesalius in his advance on Galen. The disproportions in the design have been ascribed to the conviction of Vesalius that in anatomical matters the head is more important than the hand, but Prof. Charles Singer has recently expressed the view that only the drawing of the head was by Calcar, and that the design was the work of an inferior craftsman. It is interesting to note that, of the twenty-eight oil paintings and the many other pictures of Vesalius which still exist, this *Fabrica* portrait is the only one which is considered to have been drawn from life. There is no doubt that Vesalius thought much of it ; he used the original wood block not only for the *Epitome* and the *Fabrica* of 1543 but also for the *Letter on the China Root* of 1546 and the second edition of the *Fabrica* of 1555.



The most important of the tabulae in the *Fabrica* are the three plates dealing with the skeleton and the fourteen plates of the muscles. The second muscle tabula is reproduced here. These superb drawings are really representations in line of Vesalius's conception of the science of anatomy. The body is a piece of vital mechanism, and the artist—undoubtedly inspired and instructed throughout by Vesalius himself—has positioned his dissected subjects so as to suggest the functions of the various parts. A noteworthy feature of the 1543 edition of the *Fabrica* is the landscape background in each tabula. The tabulae can be arranged in a certain order so as to give a complete panorama with a small additional picture. Reproduction gives little indication of the firmness of line and freshness of these tabulae as they appear in the original copies of the work. They certainly marked an enormous advance in the art of anatomical illustration, with the possible exception of the drawings of Leonardo da Vinci, which were not available until centuries later.

The title-page of the 1543 edition of the *Fabrica* is reproduced on page 795, but space does not permit of a discussion of the many interesting features shown by this famous woodcut. It should be noted that Vesalius is carrying out with his own hands the dissection of the female subject. The ape on the left and the dog on the right symbolize the master's readiness to use animals if the supply of human subjects failed ; indeed, many of the smaller illustrations in the *Fabrica* are of animal parts, and the book contains a section devoted to experiments on animals. The erect skeleton is perhaps an expression of his devotion to osteology as the basis of the human fabric. The naked man by the column on the left—probably used for the demonstration of surface anatomy—appears clothed in the inferior drawing of the title-page to the second edition of the *Fabrica* (1555), in which other alterations were also made. This famous plate expresses to perfection the Vesalian method of teaching anatomy, and the enthusiasm with which the teaching was received by the students of Northern Italy.

With the *Fabrica* Vesalius issued an *Epitome*, which is not merely a summary of the great work. It was intended more for artists than for students of medicine, and consists of a short text followed by an anatomical atlas. The illustrations and tabulae are frequently different from those in the *Fabrica*, and they do not appear in the text itself. There is evidence that many of the *Epitome* illustrations were completed later than those of the *Fabrica*. In various places Vesalius explains that the *Epitome* is an appendix, an index, and a compendium to the *Fabrica*. The two books are twin works, each completing and explaining the other. The *Fabrica* was finished—as the dates on the portrait show—in 1542, when Vesalius was 28 years of age. It was severely criticized by some of his old teachers, and, as he tells us in his *Letter on the China Root*, in a fit of despair he burned his books and sought service with the Emperor as Court Physician. His life with the army in the wars, his ill luck over the supposed body of a corpse which came to life, and his enforced pilgrimage to Jerusalem need not detain us. He died on the island of Zante in 1564.

There is no doubt that the *Fabrica* is one of the great books of all time, although the specialized nature of its subject has prevented its wide recognition as such. In its nearly seven hundred beautifully printed pages it contains over three hundred original illustrations, many of the highest merit. The new spirit was abroad at the time, and others were working on similar lines. Eustachius of Rome had within ten years of the publication of the *Fabrica* completed a magnificent series of forty-seven anatomical tabulae, engraved on copper. A number of these were more accurate than the illustrations of Vesalius, but one has only to compare the muscle tabulae of the two men to appreciate the superiority of design and drawing in those of Vesalius. Unfortunately the tabulae of Eustachius were not published until over a century and a half after his death. To Vesalius the real advance in anatomy is due. Of numerous structures or organs—for example, the sternum, the bones of the skull, many muscles, and the uterus—he gave descriptions which were long unsurpassed. He was the first to introduce illustrations to direct attention to comparative anatomy, and in many passages he is frank enough to admit that he had not actually seen in the human the features which he describes, but had demonstrated them in apes. Anatomy, long dead, was resurrected as a science in the month of June, 1543.

On a tomb in one of the tabulae Vesalius had inscribed *Vivitur Ingenio, Caetera Mortis Erunt.* Though the remainder of his own bodily work may have perished, the spirit of his great accomplishment lives to-day. We may perhaps be reminded, not unprofitably even now, that in an age when the dead hand of medievalism lay heavy on knowledge of the human frame the whole science was born anew and advanced beyond recognition by the faith, the enthusiasm, and the unremitting labour of a single man.

I am indebted to Dr. Charles Singer and his publishers for kind permission to reproduce the three figures from his book *The Evolution of Anatomy* (Kegan Paul, Trench, Trubner and Co. Ltd., 1925).

"PORTRAIT OF A DOCTOR"

[*From a Correspondent*]

The B.B.C.'s series of "Professional Portraits," which has included such differing subjects as a Clydeside riveter and a district nurse, struck yet another new note in the recent portrait of "The Doctor." There is something about the medical profession which can be relied on to evoke a *frisson* from the uninitiated—the remnant perhaps of the awe of priestcraft—whether it be the thrill of wonder at esoteric knowledge or a morbid association with sickness and mortality. The best-selling value of such works as *The Citadel* must surely lie mainly in the reaction from reverence which comes from the debunking of a mystery. Stephen Potter, in his portrait of a children's physician, succeeded in presenting a real person; he certainly romanticized his subject, but contrived to do so without a touch of false glamour or a suggestion of deflation.

Certain of the portraits in this series have been built upon a basis of "actuality"—that is, by a flexible use of what might be described as the technique of the interview-cum-snapshot. "The Doctor," on the other hand, was a studio performance, played by James McKechnie (as the doctor) with a very strong supporting cast; and this choice of method was amply justified in the coherence and timing of the sequences, often no more than brief snatches of conversation, whose rapid succession built up a well-proportioned picture.

The divergent appeals of medicine as a career were brought out in the talk of a group of medical students—how to one medicine means research, to another activity among *people*, to another the following of a family tradition, and so on. The medical students were excellently cast; the crudity and immaturity of their conversation were well suggested, though necessarily in somewhat expurgated form.

In the rapid flash-back in which the doctor recalls the progressive stages of his own hospital training it may perhaps have been difficult for the layman to follow each step. Too much technical language is apt to become unintelligible, while translation into common idiom loses verisimilitude. The compromise here was effective for the most part, for while a sprinkling of technicalities remained the context was suggested in plain English.

Best among the minor studies were those of the two mothers, and it was in these sequences that one realized how, whereas most doctors have to understand and convince their patients, the children's doctor can make contact with the child only through the medium of the intervening parent. Dr. Basing justified his choice of specialization in children's diseases on the ground that here, in contrast with the treatment of adults, was to be found the study of pure disease—disease in isolation. While in adults the clinical picture is confused by social habits and the wearing out of the machine, one wonders all the same whether in children it is not equally obscured by the deceits and irrelevancies of parents, who have to be studied themselves as an important feature of the case history.

BOOKS FOR PRISONERS OF WAR

As previously announced in the *Supplement* (March 20, p. 36), the B.M.A. has sent parcels of medical books to certain prison camps where numbers of its members are known to be. It has also invited individual members who are prisoners of war to send particulars of medical books they need for private study or in connexion with their camp or hospital duties. The Association had intended to ask its members at home to contribute to a fund for supplying the books required, but in order to avoid setting up a separate war charity it has now been decided that the Medical War Relief Fund will administer money subscribed for the special purpose of providing medical books for British doctors who are prisoners of war, whether or not they are members of the B.M.A. Medical men who wish to assist this work are therefore asked to send contributions to the Honorary Treasurer of the Medical War Relief Fund at B.M.A. House, W.C.1, indicating that they wish their contributions to be devoted to the provision of books for prisoners. Only subscriptions so marked will be used for this purpose, and any unexpended balance will go to the general purposes of the Fund. It is hoped that doctors at home will respond generously to this appeal and so enable the Fund to give adequate assistance to their prisoner colleagues, particularly those who are handicapped by lack of suitable reference books in their work of treating the sick and wounded in the camps and hospitals.

SIXTH ADDENDUM TO THE "BRITISH PHARMACOPOEIA"

The General Medical Council will publish shortly a Sixth Addendum to the *British Pharmacopoeia*, 1932, in which new monographs and modifications of existing monographs will be included. Under normal conditions, when a new *Pharmacopoeia* or an Addendum to a *Pharmacopoeia* has been ready for publication, it has been customary to give facilities for advance copies to be inspected, during the three months immediately preceding publication, by medical practitioners, pharmacists, analysts, manufacturers, and others who may be interested. The Sixth Addendum to the *British Pharmacopoeia*, 1932, like the Second, Third, Fourth, and Fifth Addenda, has been prepared to deal with conditions arising from the present emergency, and it is expedient that it should be published, and thus made official, without delay.

The following new monographs will be included:

Acetomenaphthonum
Acidum Ricinoleicum
Alcoholia Lanae
Chloroxylenol
Dithranol
Injectio Procainae et Adrenalinae Mitis
Kaolinum Leve
Kaolinum Ponderosum
Liquor Chloroxylenolis
Menaphthonum
Nicotinamidum
Riboflavina
Stilboestrol
Terpineol
Unguentum Alcoholium Lanae
Unguentum Dithranolis
Unguentum Zinci Oxidi Anhydrosum

The Addendum will contain, in addition, amendments to the *British Pharmacopoeia*, 1932, which have been made official by notices in the London, Edinburgh, Belfast, and Dublin *Gazettes*:

Syrupus Ferri Phosphatis cum Strychnina
Syrupus Ferri Phosphatis cum Quinina et Strychnina
Extractum Cascarae Sagradae Siccum
Ferri Sulphas Exsiccatus
Paraffinum Molle Album

and emendations to the following monographs, which will become official on the date of publication of the Sixth Addendum:

Acetum Scillae
Acidum Mandelicum
Atropinae Sulphas
Colchici Cormus
Ergota
Ergota Praeparata
Ferri Carbonas Saccharatus
Insulinum
Ipecacuanha
Ipecacuanha Pulverata
Magnesii Trisilicas
Mepacrinae Hydrochloridum
Mepacrinae Methanesulphonas
Pamaquinum
Sulphanilamidum
Unguentum Acidi Borici
Unguentum Acidi Salicylici
Unguentum Acidi Tannici
Unguentum Aquosum
Unguentum Hamamelidis
Unguentum Hydrargyri
Unguentum Hydrargyri Ammoniati
Unguentum Hydrargyri Oleati
Unguentum Hydrargyri Subchloridi
Unguentum Sulphuris
Unguentum Zinci Oleatis
Unguentum Zinci Oxidi

The Addendum will contain also new or revised appendices relevant to the monographs named above and an index. It must be understood that no additional monograph, or emendation of a monograph, is official until the Sixth Addendum has been published.

Reports of Societies

VASOMOTOR DISORDERS IN WARTIME

At a meeting of the Section of Neurology of the Royal Society of Medicine on May 20, Dr. R. M. STEWART presiding, a discussion was held on vasomotor disorders and immersion injuries as experienced in warfare.

Classification

Prof. J. R. LEARMONTH said that vasomotor disturbances encountered during total war assumed special importance in the surgery of the extremities; at the worst their occurrence might prejudice the survival of a whole limb, and at the least might lead to loss of digits or to loss of function. He suggested the following classification as a basis for discussion:

I. Vasomotor disorders resulting from injury. A. Arterial spasm: (1) local, after subcutaneous injury, (2) of collateral vessels (*a*) after arterial contusions with thrombosis, (*b*) after division of an artery; B. Traumatic arteritis; C. Traumatic venous thrombosis; D. After division of peripheral nerves.

II. Vasomotor disorders occurring in organic vascular disease. A. Syphilitic endarteritis; B. Arteriosclerosis; C. Thrombo-angiitis obliterans (1) of rapid development, (2) of slow development, (3) of stabilized type; D. Paradoxical spasm.

III. Vasomotor disorders from local effects of cold. A. Symmetrical syphilitic digital gangrene; B. Vasomotor symptoms and signs started or accentuated by (1) change of occupation, (2) change of climate, (3) high altitudes; C. Immersion foot; D. Frostbite.

He proceeded to give some brief descriptions of cases in which vasomotor symptoms and signs started or were accentuated by change of occupation or of climate or by high altitude.

An airman aged 19 went up without gloves. At 12,000 ft. he began to suffer a "fierce ache" in hands and wrists. A few hours after landing he was quite better. After this episode he had similar attacks when above 12,000 ft., although always suitably clothed. In the third of these, and in subsequent attacks, the medial three fingers of both hands became blanched up to the proximal interphalangeal joints. Four years later, although he had been employed on ground duty only, he was still having similar attacks, which were worst in cold weather, particularly in early morning. The vasomotor responses in the digits showed digital arterioles to be in a state of spasm. Full reflex vasodilatation was not reached until the feet and legs had been heated at 45° C. for 50 minutes (normal 15 to 30 minutes), although the ultimate skin temperatures (32° to 35° C.) were high enough to exclude any notable organic narrowing of the vessels.

A patient aged 25, by occupation a cinema operator and accustomed to work in a hot environment, went to Army duty in the north of Scotland. In summer, while working on the metal of a high pylon, he had his first attack, in which all the fingers of both hands became first dead white and cold, then blue, then fiery red. During the following winter these attacks became more frequent and interfered with his military duties. On clinical examination no evidence of cardiovascular disease was found, the fingers reaching full vasodilatation level in the normal time.

On the subject of "immersion foot" Prof. Learmonth emphasized the scrupulous avoidance of a too rapid return of blood flow to the chilled parts, whether induced by local heating (e.g., during first aid) or by interruption of sympathetic vasoconstrictor fibres. He had found it useful to nurse these patients on the face, with feet and legs uncovered and elevated, by an open window in default of a fan. The surgeon's attitude must be almost rigidly conservative, and this might require much patience. Formal high amputations should be reserved for the rare cases in which gangrene had been extensive or which were aggravated by sepsis. Some form of arch support should be provided in cases of paralysis of the small muscles of the feet; this should be worn during graduated walking exercise until these muscles recovered power.

Experimental Findings in Immersion Foot

Dr. W. BLACKWOOD gave an account of some histological and experimental findings in immersion foot. The human material consisted of one foot from a man who died half an hour before rescue and of tissues from feet and legs removed from survivors from 2 to 26 months after rescue. In the majority of the later cases peripheral sepsis was present. The histological appearances suggested that at the time of immersion damage was done to all the structures in the limb of a degree and to a level dependent upon the length and severity of the exposure. In particular, damage was done to nerves and muscle, with some damage to veins. Changes in skin and bone awaited further study. The nerves had the greater proportion of their axis cylinders and myelin sheaths killed. Muscles were probably damaged directly. Haemorrhage from and thrombosis of veins and venules might arise. All these changes were curiously patchy, but increased peripherally. After rescue the nerves began to regenerate. Axis cylinders grew down slowly and myelinization took place very slowly. Organization and recanalization of thrombus occurred in the veins. Muscle might await re-innervation or be replaced by fibrous tissue.

The experimental work carried out in conjunction with Dr. Russell consisted of exposing the tails of rats to cold artificial sea water for varying lengths of time and studying the changes after rescue. Patchy damage was found to be produced in nerve and muscle. In rats recovering up to two months the nerves showed persisting partial Wallerian degeneration. The muscles showed acute patchy changes similar to Zenker's necrosis, followed by inflammatory and regenerative processes and later by atrophy due to denervation. The implication was that early changes in the human might well be similar to those seen in the rats, but early human histological material had not so far been available.

Immersion Injuries due to Cold

Surg. Cmdr. C. C. UNGLEY confined his remarks to immersion injuries due to cold. True immersion foot and immersion hand, or peripheral vasoneuropathy after chilling, followed prolonged exposure to degrees of cold insufficient to cause frostbite. There was damage to peripheral nerves, vessels, muscles, and skin. During exposure the extremities swelled and there was loss of feeling. Peripheral arteries might be pulseless for some hours after rescue, and remain so in cases going on to gangrene. This short pre-hyperaemic stage was followed by a stage of hyperaemia in which the affected parts became hot, red, painful, and more swollen, the more severe cases showing blisters and gangrene. The result of damage to nerves was evident in sensory loss, and motor, vasomotor, and submotor paralysis. In the post-hyperaemic stage inflammation subsided and vascular tone recovered, skin temperature fell, and vessels might become hypersensitive to cold. Complete recovery, which in severe cases must await complete regeneration of peripheral nerves, was often preceded by signs suggesting partial re-innervation of end-organs and effector organs. Late sequels included recurrence of pain, tingling, swelling or blisters, persistence of the cold sensitive state or of hyperhidrosis, and occasionally circulatory effects suggestive of vascular occlusion.

In describing some studies in vasomotor disorders, he said that the instability of the hyperaemia in the later weeks of the hyperaemic stage was specially noteworthy. Once the feet had become cold—as, for example, by immersion in cold water or by walking on cold stone floors—they remained cold for hours in spite of all attempts to induce reflex vasodilatation. On the other hand, if they were hot to begin with, it was impossible to induce vasoconstriction reflexly. One of the characteristics of post-ganglionic sympathectomy was that the denervated vessels became sensitized to minute amounts of adrenaline such as circulated in response to insulin hypoglycaemia. Similar sensitization was seen in the hyperaemic stage of immersion foot. As the hyperaemia was passing off, often about 6 to 14 weeks after rescue, there might develop a cold sensitive state manifested either by Raynaud's phenomenon or by coldness of the feet, which took hours to warm after return to a warm environment.

Dr. J. B. GAYLOR described a case of persistently cold limbs following shipwreck two years ago, together with lack of sensation in the foot, almost to the ankle. It was possible that the low temperature of the limbs had inhibited nerve regeneration, or that owing to impairment of blood supply there was not sufficient oxygen to encourage regeneration, even though there might be sufficient to prevent loss of tissue.

Dr. RAYMOND GREENE discussed the justifiability of interference with the nerve supply in such a condition as frost-bite or immersion foot, and whether, if interference was justifiable, it should be immediate or carried out at a later time. He gave reasons for supposing the effect of any immediate interference to be either negligible or harmful, the condition of a limb after immersion or exposure being equivalent itself to that of a limb subjected to a natural post-ganglionic sympathectomy.

Sir THOMAS LEWIS said that the observations brought forward to the Section were the first reasonable ones on immersion foot, largely because such observations could be made only in time of war. It was obvious that cold had a damaging effect on tissue. In a general way that had long been known; it was merely a question of degree of cold and the duration of exposure. He took it that a person would eventually die from exposure to cold provided the cold was sufficiently extreme and the period sufficiently long. It was not strange, therefore, that changes were found when limbs were immersed for periods of hours, or perhaps days, and that those changes should affect all the tissues—skin, muscle, nerve. It seemed clear that the vasomotor system was not exceptional in this respect, and that at a relatively early stage of recovery there were vasodilatation in response to heat and vasoconstriction in response to cold. As to whether sympathectomy should be employed, it seemed to him that sympathectomy, if it was to be attempted at all, should be carried out during the later allergic stage, which seemed to produce in some way a spasmodic condition of many of the vessels in the limbs. For some of the recorded phenomena there was as yet no physiological explanation. But facts must come first, and the physiological explanation must be sought later.

At the annual meeting of the Medical Society of London Prof. G. Grey Turner was elected president.

HYPERTENSION AND RENAL DISEASE

At a meeting of the Section of Urology of the Royal Society of Medicine on May 27, Mr. H. L. Attwater presiding, a discussion took place on the relation of hypertension to renal disease.

Mr. Kenneth Heritage said that arterial hypertension, the cause of 23% of deaths in persons over 50, was outstripping cancer as a principal cause of death. Surgical interest in hypertension, excluding associated endocrine diseases, applied in three groups of cases: (1) hypertension associated with bilateral renal disease, chiefly bilateral urinary obstruction, with or without infection; (2) hypertension associated with unilateral renal disease; (3) essential or malignant hypertension in which evidence of a primary renal lesion was absent or doubtful. Hypertension was found associated with chronic urinary obstruction due to prostatic enlargement, urethral stricture, bilateral ureteric calculi, ureteric obstruction due to inflammatory or neoplastic infiltration, and a variety of other lesions. In many, particularly older, patients this might be a chance association, but a fall in blood pressure followed by a permanently lowered level was observed often enough to be a commonplace. Although these patients were frequently of advanced age and had long-standing urinary back-pressure, the hypertension was of a particularly benign type and responded well to drainage.

Clinicians had been on the look-out for cases of hypertension with evidence of unilateral disease, in the hope of affording relief by nephrectomy. Although a dramatic fall in blood pressure often followed nephrectomy, in most cases a subsequent steady upward creep of the pressure was noted until sometimes the original reading was reached again. The unilateral lesions most often associated with hypertension were trophic pyelonephritis, hydro- and pyo-nephrosis, and vascular lesions of the kidney; but he emphasized that it was exceptional to find a gross surgical lesion associated with hypertension, and it was always possible for the association to be an accidental one. The great majority of the cases were in the third of his groups, the "unknown" or essential group, and there was no evidence that the kidney was primarily responsible for this condition.

An Unknown Factor

Dr. R. W. Scarff said that the curious feature of the hypertension resulting from kidney damage was the inconstancy of its occurrence. Various explanations for the apparently fortuitous happening had been put forward—anoxaemia, excretory failure, or the formation of substances which directly or indirectly neutralized the action of the pressor substance. There was no parallelism between the event of hypertension and the amount of renal disability. He concluded from a survey of recent work that both humoral and nervous mechanisms might play a part in the production of hypertension, but that knowledge of these alone was insufficient to explain the inconstancy of the occurrence and the variations in the behaviour of this condition. A vital link in the chain had still to be sought.

Dr. Horace Evans said that there was no adequate treatment, either medical or surgical, for essential or primary hypertension. Two main groups of patients with hypertension were now recognized. In one group the hypertension was secondary to some obvious pathological state such as chronic nephritis, and in the other it appeared as the primary feature without obvious renal or other disease. Benign hypertension was a disease of later life (50–60), and ran a course of many years, often symptom-free until some cardiac or cerebral catastrophe occurred. Malignant hypertension appeared to be a separate clinical entity. It was relatively rare and found in a younger age group (40–50), with severe symptoms such as headache, dyspnoea, and visual disturbances at the onset, and in the later stages renal failure was common, with death within 12 to 18 months of onset. Papilloedema was the early physical sign which immediately distinguished this condition from benign hypertension. A careful search for unilateral kidney disease should always be made, especially in young patients. The results of nephrectomy in such patients might be miraculous, though the outcome must depend upon the presence or absence of secondary vascular changes in the sound kidney. Apart from this small group, the main group was essential or primary hypertension. Here it was of the first importance to make an accurate diagnosis of the several disorders which had so much in common in their later stages. He referred to the "hotch-potch" of conditions which masqueraded under the designation of chronic interstitial nephritis, including late stages of Bright's disease, malignant hypertension, chronic pyelonephritis, and late-stage pregnancy kidney. Particularly important was the separation of benign and malignant hypertension. A period of careful observation of symptoms, blood-pressure readings, optic fundi, and renal function was essential. Until an effective therapy was introduced it was probably true to say that the majority of patients with hypertension were better without treatment unless the state of the heart demanded it.

Errors in Search for "Surgical Kidney"

Mr. Dickson Wright spoke in particular of some errors which had followed upon the enthusiastic search for the surgical kidney in hypertensive subjects. These on occasion might be serious, even endangering the life of the patient. (1) Pyelography had been over-interpreted and minor variations and kinks had been given an exaggerated importance. (2) Kidneys might be extirpated on the basis of minor pathology to cure hypertension, with no result, so that the patient lost a good kidney and was left to fight a largely renal disease with only one kidney—a sad state of affairs. Nephrectomy was not indicated unless the kidney concerned had practically no function left or nephrectomy was indicated *per se*; in each case the operation of splanchnic and lumbar sympathectomy and possibly adrenalectomy should be done there and then, because if the patient fell among the 70% who were unaffected by nephrectomy one had at any rate done something else for his hypertension, and he required only one operation more to complete the treatment on the other side. (3) The kidney exposed at the first splanchnic resection might be found to be grossly diseased, and although pyelography might be normal the surgeon might be tempted to remove it there and then, to refrain from splanchnic resection on account of the gross renal pathology, or to go back and remove the diseased kidney later if sympathetic surgery failed. Mr. Wright described cases illustrating these points. One of them illustrating the first and third of these alternatives was the following:

A woman aged 26 had severe eclampsia with her third child and was left with malignant hypertension. Course downhill in spite of all treatment. At her first sympathectomy kidney found to be markedly granular, with a raspberry-like surface. Agreed with physician that first kidney would come out later if bilateral sympathectomy a failure. At second sympathectomy the other kidney looked normal, but a biopsy was done, and the section was indistinguishable from that of the grossly diseased kidney; both showed gross renal pathology. If biopsy had not been done a serious error might have been made.

The importance of the surgical kidney should be written down rather than up. A biopsy of the renal parenchyma in hypertension should always be made. The sympathetic nerves in a renal operation should always be cut if hypertension was present.

In a Chadwick lecture on "Plants causing Irritation," with Sir William J. Collins, M.D., in the chair, Mr. F. J. Chittenden said that a considerable number of plants met with wild, or cultivated in gardens in England, were apt to irritate the skin or the nose and eyes of those handling them. Some, like *Primula obconica*, were well known to be suspect, but many were unsuspected, and sometimes the result of contact with them was not only irritation but general discomfort and, for the time being, incapacity for work. These symptoms had not infrequently been attributed to other causes, with failure to obtain relief. The study of such afflictions was complicated by the well-ascertained fact that, while some persons were susceptible to irritation by one plant, others suffered far less from it or might escape altogether, though susceptible to irritation from some other plant. Most of these disorders, except for the various forms of hay-fever, only followed actual contact with the foliage or stems of the irritating plant, and some of the primary causes of irritation acted only through wounds in the skin. The wounds might be very minute, like those made by the hairs of the stinging nettle, or, in very thin skins, by the needle-like crystals abounding in the sap of the daffodil and many other bulbous plants. Knowledge of the range of plants capable of causing such troubles might give pointers in the search for the causes of some obscure skin affections, or of running at the eyes and nose, and a chance of avoiding them.

Correspondence

Psychotherapy in General Hospitals

SIR,—Dr. Dalton Sands's article and your editorial of May 22 have raised vital issues. Dr. Rees and Dr. Shepley express disapproval of the policy advocated, while Dr. Dillon warmly supports it. I venture to suggest that the issue, as raised by these correspondents, is a false one. Indeed it would seem as if we were witnessing the unedifying spectacle of competition within the profession for the privilege of treating a certain group of patients.

Putting aside such subsidiary questions as the feelings of relatives and the so-called "stigma" of the mental hospital, we have to deal with a single fact in reality—namely, the inevitable locked gate of the mental hospital and all that it rightly represents in the way of legal supervision and protection. The locked gate is for certain patients necessary, for others unnecessary; for some it is helpful, for others the reverse. The therapeutic resources on both sides of the locked gate should be equivalent. They are far from being so now, and in consequence we have the anomalous situation of patients being persuaded to pass the locked gate by the assurance that though they have no need of supervision or restraint yet only behind the locked gate can the necessary treatment be secured. Conversely, if, as some of us hope, therapeutic resources, such as electric convulsant therapy, become generally available at open hospitals, we shall have to face increasingly the pleas of patients, relatives, and often family physicians: "If the proper treatment is available at the general hospital, surely the patient needn't be condemned...."

It follows therefore that psychiatrists will be called on to make more definite diagnoses of what may be roughly defined as certifiability, and on that issue *alone* to decide the disposal of the patient, in the full knowledge that the decision will not limit or even modify therapeutic possibilities. And it may be hoped that, if such a state of affairs is achieved, the psychiatrists on both sides of the locked gate will co-operate with good will and an objective outlook on clinical realities.—I am, etc.,

London, W 1. H. CRICHTON-MILLER.

SIR,—Dr. T. P. Rees and Dr. W. H. Shepley in their letter (June 12, p. 735) make several statements which are open to criticism.

First I should like to point out that, having been a member of the medical staff of a mental hospital for many years, I am well aware of the extremely good work which goes on in such hospitals, and I should be the first to deprecate the fact that mental hospitals should be used solely as dumping grounds for the chronic, incurable patient. On the other hand, I maintain that there are many types of patient who are definitely unsuitable and unwilling to enter mental hospitals on a voluntary basis because of the impossibility of complete segregation. Many of those suffering from neuroses and early psychoses (socially well conducted) resent going into mental hospitals, as even though they are housed in separate villas or admission units in the mental hospital they of necessity meet the chronic patients on common ground—viz., at occupation, recreation, in the grounds, etc. Would Dr. Rees and Dr. Shepley prefer that these patients, therefore, because of their unwillingness to enter a mental hospital, remain untreated until they become certifiable, or their illness becomes so chronic that the chances of recovery are considerably diminished and in any case is probably prolonged by months?

Secondly, this hospital makes no claim for the originality of the methods of treatment employed. Dr. Rees and Dr. Shepley state that these methods were already proved in the modern mental hospital. This is rather a sweeping statement. Are they proved? I, personally, am not convinced that such methods of treatment as electro-convulsive therapy, insulin, etc., are not still in the experimental stage, and that many more years of research are necessary to *prove* these methods. Did they originate in Warlingham or other mental hospitals? So far as I know, they were first employed in American and Continental neuropsychiatric clinics and were then tried out in this country.

The fact that the number of admissions to Warlingham Park Hospital has increased from 125 in 1932 to 277 in 1942 is somewhat surprising, as throughout the country the number of admissions to mental hospitals has decreased appreciably during the war years. Why, then, does the Croydon area differ in this respect?

Regarding the financial aspect, I agree with Dr. Sands that many of these cases, if treated later because of their unwillingness to enter a mental hospital in the early stages of their illness, would have required prolonged hospitalization involving more economic distress to their dependants and a heavier financial burden to be borne by the hospital. The comparison of the maintenance rate at Sutton with that of a mental hospital established in peacetime and built as such is hardly fair. This hospital was an upgraded institution which had to be adapted for hospital purposes and is continually being adapted at the present time. In my opinion, after this war there will be a place in psychiatry for the neuropsychiatric clinic in the general hospital, psychiatric units for acute and short-term disturbed cases, and for the mental hospital. The last would still have a cross-section of all psychiatric cases and continue to carry on the good work which it is doing at the present time.—I am, etc.,

Emergency Hospital, Sutton. LOUIS MINSKI.

Selecting the Medical Student

SIR,—So it seems that the planners are now getting busy with the prospective medical student. No longer will boys or girls say that they are going to be doctors, but must wait until they have been before a board to see if these mandarins will allow them to be so. Suppose a candidate is rejected, is there to be any appeal? Will he be told why he is not suitable? Then suppose the rejected tries something else, is another board going to tell him he can't be that?

Let us get rid of these attacks on our freedom before it is too late, and we find we are a nation of spineless individuals with no say in our future or that of the children. It is an astonishing fact that such interference should be suggested, and is a sign of the times, when all initiative and liberty are being taken from the public. Personally I should not presume to tell anyone what his future career cannot be. With much more interference the press gang is more likely to be needed to gain entrants to the ranks of the medical profession.—I am, etc.,

Sheffield J. A. WOOD.

Planning of Medical Education

SIR,—Dr. C. F. V. Smout, in his letter (May 29, p. 676), offers destructive criticisms of a few of the suggestions put forward in my article on medical education (May 1, p. 547). These criticisms, apart from indicating an attitude of complacency and satisfaction on the part of Dr. Smout, are largely invalid, in that their author has indulged in the practice of lifting a statement from its context and ascribing to it a significance not intended in its proper setting: this applies in particular to his remarks on co-ordination of the anatomy of the body as a whole. I hoped that I had made it clear that the time saved by rendering unnecessary the repeated revision of minute details would be available for such correlation; at present the student is fully engaged in acquiring new minute details and attempting to revise ones already noted right up to the eve of his professional examination, and it is common experience that he has no time to take a broad view of the human body and acquire a thorough understanding of the important principles involved. Then Dr. Smout asks, "Who *is* placing a premium on feats of memory?" May I *truthfully* reply that both Dr. Smout and myself are sinners in this respect?

Dr. Smout accuses me of being out of date regarding the relationship between universities and the Ministry of Labour. I can assure him that no school is more strict than my own in its duty to the State in this connexion, and would inform him that his horizon must be limited if he is unaware of the large number of students in Great Britain who descended from degree to diploma in the immediate pre-war days; although war measures have temporarily diminished this number, this does not affect the ultimate issue.

Finally, with regard to Dr. Smout's complaint concerning the length of time required to interview prospective entrants, I would impress on him that the importance of this interview of a person on the threshold of his proposed life's career is becoming generally appreciated, and, while a proportion of the candidates may be eliminated by means of the entrance examination, coupled with a survey of their previous records (as envisaged in my communication), even if the time devoted to interviewing the remainder approaches that calculated by Dr. Smout, it would be time which, in the view of many, would be extremely well spent. In effect, I hope Dr. Smout will turn his mind towards constructive effort, as I am sure he must be aware of the widespread dissatisfaction felt concerning the present state of affairs.—I am, etc.,

University of Sheffield. F. DAVIES.

Future of Medical Services

SIR,—Our medical Peers and Dr. Charles Hill by their statesmanlike and practical speeches, reported in the *Journal* of June 12, have so qualified the discussion on medical services that we must all feel grateful to them. We seem to have been delivered from a state of hopeless confusion that had little apparent prospect of decision; there has been of late a tendency to widen again the closing gap between preventive and curative medicine, but these speeches should help to stop such a disastrous move.

What private practitioners, consultant or general, are anxious to know is: What form will local authority take, and in what way, if at all, will it interfere with their professional lives? It appears that these influential speakers envisage a local authority, not our present-day county or municipal council, but an *ad hoc* health authority which may well be so constituted as to be democratic and acceptable to the medical profession. It has often been stated that there is no urgent need to set going any new scheme, and the Dawson Consultative Council more than twenty years ago was of opinion that the only satisfactory way of finding out what was wanted and what could be done was to set up an experimental health centre.—I am, etc.,

Westbury, Wilts CHAS. E. S. FLEMMING.

Doctors and the Future

SIR,—Mr. A. B. Rooke and his co-signatories (May 22, p. 649) asked the very question to which I have tried, without success, for some time to obtain an answer. I beg your indulgence and valuable space, since no one has yet answered this group their vital and very pertinent question, to ask this question again: Since the Government considers a drastic reorganization of the medical profession and extensive changes in the conditions of medical practice urgently necessary, can we not be told what it is considered that is wrong now?

It might seem to many of us that this explanation is a prime necessity, owed to us at the outset, and one that should have been made clear at the beginning before the discussion of schemes started. It is not doubted that there is room for great improvement, nor can it be questioned that great improvements have steadily evolved since the last war, but there will still be room for further and continuous improvement even after any new Government scheme for a comprehensive medical service has been brought in.

A second question arising out of the above is: Who is really behind this desire for drastic change? Is it purely political? I know of no such agitation or demand on the part of the general public.

Lastly, since the present National Health Insurance scheme is, at the moment, the chief form of State medical service or scheme, why is not this scheme to be modified, and, building on the existing foundations, made a really first-class, comprehensive, and complete medical service for the bulk of the populace? In the present panel scheme we have at least the nucleus of what could be made a comprehensive medical service for the great majority. Is the N.H.I. scheme to be "washed out"? As Lords Dawson and Horder have so wisely urged, we should build upon existing foundations, and gradually improve and evolve. It is not a happy augury for the Government's future scheme that their existing one (N.H.I.) should be a byword in many respects; for it is still rather regarded as an insult than an honour to be termed "panel"! Millions of our people are ashamed of belonging to it.—I am, etc.,

Hassocks. CHARLES A. H. FRANKLYN, M.D.

Proposals and Discussions

SIR,—The Secretary of the B.M.A. and the Chairman of Council have ruled that to question whether the country or the profession wants the Beveridge plan is to challenge the British Constitution, since Parliament—*vox populi*—has tentatively accepted the proposals. This is a specious argument bearing no analysis. It is all a question of what is reasonable. Parliament has no more right to coerce the medical profession against its will than it would have to order Anglican clergy to practise Roman Catholicism. Trade unionism is a direct consequence of the recognition of the right of the worker to a hearing.

At the joint meeting held on March 31 last the Chairman of Council said: "The Council regarded the Beveridge report as of such importance as to call for reports on its proposals from certain of the standing committees." Would it be impertinent to suggest that the proposals are of such importance as to justify an inquiry of the whole profession? Such an inquiry is expected as of right of membership of the B.M.A. There is, in more senses than one, no doubt of the way in which the Ministerial mind is working. The present position is that whatever Bill is presented to Parliament will possibly meet with the approval of half a dozen members of the discussions committee. But there is no more guarantee that the Bill would be modified in deference to popular medical opinion than that the original proposals for a State Medical Service will not be introduced.

On Feb. 13 last it was announced that special meetings were to be held on March 31. The motion to be debated, as framed, afforded a very poor occasion for full discussion, but it gave some the opportunity to contradict Sir William Beveridge. However (perhaps by skilful tactics), the Minister precipitated Council into entering into "discussions," thus effectively depriving the rank and file of the profession of their only chance of an expression of opinion. The Beveridge report is a major political issue, and, while it is clear that the Minister intends to introduce legislation at the earliest moment practicable, it is equally clear that he will not risk a Governmental defeat. Thus his primary concern is the possible reaction of about 400 Members of Parliament, while the reactions of about 40,000 practitioners are as much "in the discard" as the preliminary discussions. Had this not been so the Minister would have continued to attend all the discussions in person.

The demand for a Royal Commission had a salutary effect, for the committee was able to negotiate the postponement of the White Paper. This was reported in the *Daily Telegraph* as a "concession to doctors." It was nothing of the sort. The question of a State Medical Service had not arisen. The withdrawal of the request for a Royal Commission was, however, a concession to the Minister in consideration for his undertaking to honour his promises. Meanwhile we must wait impatiently to learn the basis of the continuing discussions. I will hazard the guess that the basis is the Draft Interim Report of the Medical Planning Commission, about which the Chairman of Council said at the last Annual Representative Meeting "there need be no fear that anything would be done without full consultation."

Much has been said of unity in the profession. Unity cannot be achieved without acknowledgment of other points of view. Unity is the basis of stolid government the very foundation of which is based upon the existence of an official opposition. This is the sort of thing the British Constitution provides for. It should not be beyond the ability of Council to devise some similar machinery. Applied to Representative Meetings, the effect would be stimulating to thought and conduct. Unity is achieved by sinking differences after they have been acknowledged to exist. Council must by now be strangely lacking in this respect. Had the profession been consulted earnestly and promptly the Minister would never have dared to trifle with us. Had propaganda been wisely directed, the doctors would not yet be judged as seeking concessions. At this eleventh hour the effort to achieve unity would still be small, but the purpose remains very high. As matters stand the Minister will make proposals calculated to meet with the approval of Parliament. That will be that.—I am, etc.,

Watton-at-Stone MAURICE E. WIGFIELD.

"In the Discard"

SIR,—I would like to draw attention to the most timely warning you give in the last sentence of your excellent leading article under this heading (May 29, p. 670) and also to endorse your advice to read the report of Dr. Charles Hill's speech (*Supplement*, May 22).

The Beveridge Assumptions C and A and the housing question will most certainly exercise the minds of those who have to find a living to a much greater extent than will problems of health or education. Unemployment and bad housing will never allow of "positive health"; to offer the electorate a nationalized medical service instead of work and proper shelter would be grossly unjust and intolerable. It is unnecessary to repeat here all the reasons against a whole-time salaried service; but as a vote of almost 90% was cast against such a service at the A.R.M. in 1942 it behoves those of us who are of this mind to continue to support, actively, those of our officials and leaders who have shown that they appreciate that this is not the best way in which we can render our services to the community.

However well it may work in some special services, the State official (or local government authority official) can be no substitute for the "family doctor." Of this the patients are well aware from past experience. Our new "publicity" must warn the people that, in spite of the promises of politicians, the imposition of such substitution has been the basis of Ministerial proposals; whereas B.M.A. proposals are based on the best interests of the individual patient.—I am, etc.,

Chester. DAVID R. OWEN.

Radiologists and the Future

SIR,—There are some points in Dr. Norman Henderson's letter (June 5, p. 710) that call for comment. The replies to Dr. Henderson's questionary indicate that 57% of the radiologists prefer to continue their private practice in their own rooms, while the replies to the questionary issued by the Faculty of Radiologists show a majority of 2 to 1 in favour of conducting their diagnostic *x*-ray private practice in their hospital or hospitals. This disparity is possibly explained by a difference in the type of practitioner consulted. The membership of the Faculty is restricted to those exclusively engaged in radiology in one or more of its branches, and the Faculty's questionary was submitted to its members only. Dr. Henderson's questionary was submitted to a wider field, including medical men engaged in general practice as well as radiology. In reply to the Faculty's questionary an overwhelming majority of radiotherapists expressed their agreement with concentration of all radiotherapy, private and hospital, into large units. Regional organization as outlined in the Memorandum on Planning of Radiotherapy for Great Britain issued by the Faculty is in keeping with that opinion and with present-day needs.

The Faculty is one of the appointing bodies to the Medical Planning Commission organized by the B.M.A., and subscribed to the general principles embodied in the Interim Report of that Commission, in which respect it is in agreement with the great body of medical opinion in this country. The Faculty, in its Memoranda on Radiodiagnostic and Radiotherapy Services for Great Britain, certainly supports the principles of regional organization of those services, but there is nothing in either memorandum to warrant Dr. Henderson's suggestion that it favours the idea of a whole-time salaried State Medical Service.

The mainspring of Dr. Henderson's recent activities seems to be an apprehension that the interests of radiologists are not being watched in these times of impending change, but as he is not a member of the Faculty he is perhaps not fully informed of how much the Faculty has been doing in this respect. Its members have been consulted by questionary on the broad principles involved; its Council has been in arduous session throughout the past three years, has submitted the two Memoranda above mentioned, and has, at the request of the Goodenough Committee on Medical Schools, produced two further reports on radiological education. The Faculty is in close co-operation with those bodies charged with negotiation with the Minister on the medical service of the future; and at the invitation of the Joint Committee of the three Royal Colleges has appointed a committee, which is now in session, to advise on radiological matters.—I am, etc.,

S. COCHRANE SHANKS.
London, W.1. President, Faculty of Radiologists

Haemolysis in Blackwater Fever

SIR,—I have just received your issue of March 6 and read the paper on haemolysis in blackwater fever by Felix Smith and R. Winston Evans (p. 279) with very great interest. In these days of disruption it is obviously not easy to get at files of the smaller journals, and so I attach no blame whatsoever to the authors for believing that their alkaline treatment is a "new rationale for the treatment of intravascular haemolysis." I enclose a reprint of my paper on "The Biochemical Aspect of Blackwater Fever" from the *West African Medical Journal* of as long ago as July, 1932. This reprint gives the alkali treatment in great detail, and I still insist on the importance of glucose in the matter. Up to 1934 I knew of thirty-four cases treated as I advocate and there was one death. Since then I have treated four cases in Jamaica with no deaths.

In the same mail *Nature* of Feb. 27 contains a letter from Maegraith, Findlay, and Martin, who are in West Africa, in which the authors announce their discovery of a red cell lytic enzyme in organs which include the liver and spleen, and an enzyme which occurs in serum and tissues. Such a discovery follows the rule of enzyme action, and the sites of production are exactly those that would be postulated by the reasoning in my paper of 1932.—I am, etc.,

Kingston, Jamaica W. E. McCULLOCH.

Tuberculosis and Exposure to Infection

SIR,—Your correspondent Dr. Basil Sampson (June 5, p. 708) happens to have forgotten the factor of personal resistance in his remarks on bovine tuberculosis in South Africa, which illustrate the common tendency to assume that everyone exposed to tuberculous infection will sooner or later become tuberculous. Although it may be good policy to regard everyone so exposed as potentially tuberculous, it is common knowledge that only a small fraction of such persons develop tuberculosis. Whether they do so or not depends partly on inheritance, but largely on habits and conditions of life; and where there is evidence of exposure to such infection, these constitute the first thing to investigate and if necessary to set right.

In spite of the great advances made in diagnostic technique, there is still need for a good laboratory test to distinguish between those who are beginning to develop tuberculosis and those who are in no such danger.—I am, etc.,

Farnham, Surrey F. R. WALTERS.

Advice on Sterility

SIR,—It is difficult to understand why Dr. R. H. P. Hick is so annoyed with Lord Horder. On his own admission he sends his sterile patients to a gynaecologist, who investigates the couple more or less completely and sends them back to Dr. Hick with reports and advice as to treatment. This is precisely what the medical officer at a clinic does if the patient is sent there by a general practitioner. But what of all the unhappy couples who are not so blessed as Dr. Hick's patients and whose medical advisers shrug their shoulders and say, "Go home and keep on trying," or, to the wife, "You could have a D and C done"? With regard to this business of numbers—though numbers are necessarily used at clinics, as in hospitals, for purposes of filing and records—it may ease Dr. Hick's mind to know that the patients themselves are invariably addressed by their proper name and title. Are clinic doctors necessarily more inhuman and unsympathetic than gynaecologists, and is the sweeping statement that "a State Medical Service is unwanted by doctors and patients" true? It is nice to know of the faith that Dr. Hick's patients, no doubt justly, repose in him, and of how successfully he and his gynaecologist collaborate to fight sterility, but it may be pointed out that if a couple is by them ranked as sterile "after even a few months" this may account for a proportion of their successes. Incidentally, how is our knowledge about this exceedingly complex problem to grow unless there is some co-ordination of methods and accurate recording of observations over a period of many years?—I am, etc.,

Crediton, Devon. MARGARET C. N. JACKSON.

Oedema of Extremities at Sea

SIR,—In the matter of Dr. H. E. Thorn's letter (June 5, p. 708) on oedema of the feet and ankles in fit men during a voyage, may I offer the conjectural fruit of my experience? I was on a liner for four years which crossed the Tropics every month, and this oedema was a regularly recurrent trouble in hot weather. So far as the crew were concerned—and they were supposed to be fit men—it often affected the same members voyage after voyage; it was confined to the victualling department—i.e., stewards, cooks, etc.—the deck and engine-room departments did not suffer. Rubber soles were an obvious factor in every case; habitual "scurriers"—e.g., bedroom and saloon stewards—were the worst victims; leather soles or cold weather relieved the condition. All the passenger accommodation on this ship—cabins, alley-ways, and public rooms—was decked with some rubber compound, and from these and other facts I came to the conclusion that the main cause was the insulation which this and the rubber soles made complete, and that an accessory one was the friction on the sole and dorsum of the foot which the abrupt rubber to rubber contact on walking created. So far as troops on transports are concerned bare feet for at any rate part of the day are the best preventive and cure.—I am, etc.,

Beckley, Sussex. C. G. LEAROYD.

Nasal Intubation

SIR,—I have never been able to understand the objection by the rhinologists to this method. Is it because it was developed by the anaesthetist and not by the rhinologist? The article by Mr. A. R. Dingley (June 5, p. 693) is interesting, but it gives no more than the usual precautions which every anaesthetist takes when he employs this very useful procedure. Mr. Dingley admits very few complications, and at the same time suggests "lack of anatomical knowledge of the nasal cavity," faulty technique, etc. If an anaesthetist does not possess the anatomical knowledge—which I very much doubt—or is guilty of faulty technique, it is no reason why the method should be condemned. I think there is very little danger of doing harm if reasonable care is used—and it should be used in all procedures. I have seen much more damage done by the inexperienced during the oral approach than I have by the nasal one. I have seen one or two sanguinary encounters when an inexperienced anaesthetist has spent his time removing divots from the pharyngeal wall. Nasal intubation by a Magill tube is, to my mind, quite safe with reasonable care, and I have seen a life saved by the method when a lung abscess ruptured into a bronchus. The anaesthetist had not time to assemble the laryngoscope, but intubated blindly and suctioned. The patient made an uninterrupted recovery.

Mr. Dingley cites two cases which are of special interest: the first where the enthusiastic anaesthetist produced two pints of blood from the nose, and a second where a case of adenoids was nasally intubated. These two cases were obviously instances of wrong technique, but they did nothing to condemn the method. I think the method is ideal for oral surgery and especially for difficult dentistry.—I am, etc.,

J. B. H. HOLROYD,
Anaesthetist, Sheffield Royal Infirmary.

SIR,—Mr. A. R. Dingley in his article on nasal intubation (June 5, p. 693) says: "It is clearly unwise to pass a tube through a nasal passage the interior of which is a closed book to the introducer." I would point out that the experienced anaesthetist, when passing a nasal tube, gently explores the nasal airway, and can diagnose by means of his tube the nature and position of any obstruction that he may meet without inflicting injury on the mucous membrane, in the same way that a surgeon may diagnose the type and position of an obstruction in the urethra by means of a sound or catheter. This renders unnecessary the previous visual examination of the nasal airway, which Mr. Dingley advises should be done after cocainization and with a head lamp.

Mr. Dingley gives no figures, but hints that virulent sinus infection is not very uncommon after nasal intubation for tonsillectomy. In my experience it is not common or virulent, one mild sinus infection having occurred in 500 cases (all soldiers) which were nasally intubated for tonsillectomy. Hewer in *Recent Advances in Anaesthesia* quotes 500 consecutive cases of nasal intubation for tonsillectomy without a complication sufficient to prolong the patient's stay in hospital.—I am, etc.,

Colchester. DOUGLAS CLENDON.

Social Insurance and Medical Practice and Research

SIR,—Dr. E. M. Fraenkel, in his most interesting and suggestive letter (May 8, p. 583), points to the important part which university clinics on the Continent have played in scientific research. May I add that the part which sickness insurance on the Continent has played in this matter is just as notable. While, under the British system of health insurance, approved societies and insurance committees were hardly in a position to show much interest in the progress of scientific research and its socialization, the municipal and other sickness funds on the Continent have regarded this part of their duties as the most essential one.

Let me quote for this a description which Dr. G. F. McCleary, formerly a deputy senior medical officer of the Ministry of Health, has given in his book on *National Health Insurance*, 1932, page 53: "The General Local Sickness Society in Hamburg, for instance, has four institutes for artificial sunlight therapy, where about 7,000 persons are treated annually, and a large orthopaedic institute to which is attached a workshop for making appliances. Diagnostic facilities are provided on a large scale. The Institute of the Association of the Berlin Krankenkassen (sickness funds) contains chemical, pathological, bacteriological, and serological departments, and makes 5,000 to 6,000 examinations monthly. The miners' benefit societies have founded a number of hospitals, many of which are models of their kind, for the special needs of the population." No wonder, then, that, as McCleary observes, "the extensive range of the medical services provided by the German scheme brings the insurance societies into close relation with the great body of the medical profession in Germany."

To all those who, in common with the views often expressed by the International Labour Office in publications on social insurance, emphasize the organic, and indeed dynamic, link between medical science and sickness insurance administration, it must come as a shock that the Beveridge report aims at widening the gap already existing in this country between social insurance and medical practice and research. Social insurance funds will be entirely "separated" from medical service and research, to which they will only contribute just as a tax-payer contributes to the needs of the country. The ambition of local sickness funds to set up—in their own interests as well as in the interests of a higher human aim—the best possible service and to attract to it the best men of practice and research will be eclipsed in favour of a State scheme, of which we cannot say when it will come, what its comprehensiveness will be, and how far it will leave open the door for individual exertion so necessary in that great science—medicine.—I am, etc.,

Richmond. HERMANN LEVY.

V.D. in the Merchant Navy

SIR,—I welcome Dr. J. C. H. Browne's exposure (May 22, p. 645), after a first-hand experience of it as ship surgeon, of the discreditable state of affairs that may still obtain at some ports and times to impede the proper medical care of the merchant seaman infected with venereal disease. Now Dr. Browne records his observations of the dire results to seamen, and the public health, of the absence of hospital accommodation for venereal disease at ports, and the interruption of other peacetime arrangements for continued treatment at ports of V.D. in seamen; while the third year of war found us in full and public agitation over the increase of V.D., especially in seamen and in the populace of our ports.

I feel sure that medical opinion can rightly be unanimous in pressing for: (1) in all ports, facilities for treatment that do in fact facilitate the seaman's finding treatment and keeping under it; (2) instruction in V.D. of the medical profession in general, and the ship surgeon in particular; (3) proper equipment for adequate treatment of V.D. in ships that carry surgeons; (4) serious consideration to be given to the fact that in ships that carry a surgeon only a minority of seamen who have cause do consult him for suspected or apparent V.D., although the seaman heartily dislikes visually apparent V.D. either in himself or in his shipmates.

Since the very great majority of ships carry no surgeon the seaman, by long-established custom, keeps his ailments for medical attention when he gets ashore—if by then they still distress him. The idea of treatment on board ship is perhaps still foreign to the merchant sea-going profession. Moreover, in the past, treatment of V.D. on board ship could be, at best, only inadequate; it was hardly better on shore; and while the last three decades have brought a great improvement of treatment, it has lagged at sea far behind the standard on shore. There is still some foundation for the traditional idea in the seaman's mind that not much benefit will accrue to him from bothering the ship surgeon on such a matter. The main barrier, however, keeping him from the ship surgeon in the matter of V.D. is dislike and suspicion of its being logged against him—as by law it must be if his ship surgeon deals with it. The same seaman, however, evinces no objection to the hospital doctor's logging V.D. against him in a clinic's records, even when done in his presence. The ruling difference appears to be not only that the clinic is publicly pledged to secrecy—though that is highly valued—but also that the hospital doctor is not his boss, and the clinic books are not open to inspection by bosses—master, mate, owner—as is the ship's log. Easy to understand, not easy to reform, yet reformed it ought to be.—I am, etc.,

H. M. HANSCHELL,
Director, V.D. Clinic,
Albert Dock Seamen's Hospital.

London, E 16

The Contaminated Injection

SIR,—Your annotation on the contaminated injection (May 15, p. 608) draws attention to the problem of filling a hypodermic syringe with sterile air under adverse surrounding conditions, and suggests a cumbersome procedure as a solution. The problem is simply overcome by using a platino-iridium needle and a spirit lamp. A platino-iridium needle can be raised to a white heat in a spirit flame without harm, and while holding its point in the flame and at the same time withdrawing the piston you have a medium through which sterilized air can be drawn and which no spore can withstand. I have used this method many hundreds of times without harming the needle or the glass syringe. It has the added advantage that the same needle can be used where many injections have to be given at one sitting, it being perfectly sterilized each time. The ordinary needle could be used in the same way in an emergency, but it would be quickly ruined by such treatment.—I am, etc.,

Portland. M. J. SAUNDERS.

Universities and Colleges

UNIVERSITY OF MANCHESTER

A one-day course of lectures on health in the factory has been arranged for industrial managers on Sunday, July 4, by the Extra-mural Department of the University in conjunction with the Association of Industrial Medical Officers. The course begins at 10.45 a.m., when Dr. H. Trumper will speak on the responsibility of management for the health of the worker, followed at 12 noon by Dr. T. M. Ling on psychological factors in industrial health. At 2.15 p.m. Mr. G P. Barnett will speak on management's part in accident prevention.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following candidates have passed the Primary Fellowship Examination:

R. C. Bell, D. T. A Brown, B N. Catchpole, B S. Crawford, J. F Dark, F. X. Darne, J R G. Edwards, E J. Field, J P Haile, A. G. Leacock, R. I. T. Lloyd, S. T. McCollum, R A. C Owen, V. G. Patel, R D Richards, Mary F. Richardson, R B K. Rickford, F Robinson, K E D Shuttleworth, G. F. Smart, J. B. L. Taylor, G. T. Watts, M. R. Williams

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

Sir Henry Dale, G.B.E., P.R.S., will deliver the Frederick Price Lecture on "A Prospect in Therapeutics" in the Hall of the College on Friday, July 2, at 5 p.m.

Obituary

SIR ARTHUR NEWSHOLME

Dr. J. D. ROLLESTON writes:

The sympathetic obituary of this great man in the issue of the *Journal* for May 29 has an important omission—namely, the lack of any mention of his keen interest in the alcohol problem. For many years he was a member of the Society for the Study of Inebriety and Drug Addiction, and in 1927-9 was its president. In 1928 he attended the 19th International Congress against Alcoholism held at Antwerp, where he delivered a masterly address on "The Place of the Alcohol Question in Social Hygiene." His *International Studies* (1931) contain an instructive account of anti-alcohol activities in Denmark, Sweden, Switzerland, Italy, Yugoslavia, Poland, and Czechoslovakia, while his work on *Red Medicine* (1933) gives a description of the campaign against alcoholism in Soviet Russia.

Sir FRANCIS FREMANTLE, M.D., M.P., writes:

Your tribute to Sir Arthur Newsholme mentions his work on tuberculosis. I would remind your readers of his report to the Local Government Board and his article in the *Journal of Hygiene* (July, 1906, **6**, No. 3) showing the special influence of segregation in workhouses and workhouse infirmaries in the reduction of the phthisis death rate. The breadth of his inquiry in this and other countries, the thoroughness and honesty of his statistical evidence, the credit given to other known factors, the searching criticism of accepted argument, gave a new and convincing proof of the value of the abused Poor Law and of institutional treatment as such. As a young county M.O.H., on a pilgrimage to him at Hove some 40 years ago, I had much valuable advice, of which one phrase has endured: "Study vital statistics, Fremantle; they will prove anything you want." I always wondered if he meant "prove" in the Pauline sense.

The following appreciation of EDWARD HARTE, M.B., B.Ch., D.P.H., deputy medical officer of health, Harrogate, comes from Dr. D. Derry Payne, medical officer of health, Harrogate, and Dr. J. Tudor Lewis, medical officer of health, Barnsley: We would not wish the recent sad death of Dr. Edward Harte to pass without paying a tribute to his strong character and great personality, qualities which enabled him to bear the bludgeonings of a hard fate with a laugh and a joke. We first knew him when he joined the public health staff in Croydon. A slowly progressive illness "accidentally discovered" had caused him to give up his practice in Blackpool. After taking his D.P.H. he entered the Public Health Service and very soon became a great success. When one of us went to Harrogate as M.O.H., Harte soon followed as deputy. He was outstandingly successful with children, and the mothers all had an abounding confidence in him. To the many administrative problems of a public health department he brought a sane common sense, and he had the gift of making himself liked by all his colleagues, medical and lay. What attracted people most was perhaps his great spirit and sense of humour. He could and did see fun in everything, and his quickness of phrase and richness of expression were astonishing. Although he knew he was doomed we never once heard him complain of his fate; he rather liked to joke about it, and when he got a retinal haemorrhage he was amused and laughed that his senior colleague "had bought a pup." This was typical of Harte. Reading was his main relaxation, but at one period he had played a good game of golf. He was also a very keen bird-watcher, and his knowledge of this subject was extensive. We have lost a dear friend and a valued colleague. The profession generally and the Public Health Service in particular will be much the poorer by his untimely passing.

Dr. W. HENDERSON STEPHEN died at Southend-on-Sea on May 28 in his 75th year after a long illness. A graduate of Aberdeen in 1891, and of farming ancestry, he had fought his way by his own tireless industry and settled, first at Preston, and later, for 20 years, at Smethwick, where he built an outstanding practice by his thoroughness and by his kindness, cheerfulness, and sense of humour. He had been an ardent Territorial, serving 1914–16, and retiring as lieut.-colonel. Settling in partial retirement at Southend, he again achieved a successful practice until two years ago, when his health failed. He had been a member of the B.M.A. for nearly 50 years and was a past chairman of the South Essex Division.

Medical Notes in Parliament

THE GOVERNMENT'S PROPOSALS

Dr. RUSSELL THOMAS on June 10 drew attention to the negotiations between the Minister of Health and the medical profession. He said the House should have some idea of these before the White Paper was published. At a meeting on May 16 the Deputy Secretary of the B.M.A., Dr. Hill, spoke on the proposals put forward by the Minister. Put briefly, these were that medical men would cease to practise freely as doctors and would become whole-time employees of local authorities. If this happened doctors would form a service of technicians controlled by men and women ignorant of medical matters. The objections to the local authority arrangement had been set out by Dr. Anderson, Secretary of the B.M.A., in a letter to the *Times*. The main objection was that the medical profession would be in the hands of the local authorities, people who were frequently under the influence of party politics, and could not understand the vital personal relationship which existed between doctor and patient. In any case the scheme put forward by the Minister would lack the comprehensiveness which was an essential of the Beveridge plan. The proposals for a consultant service were vague. They were to be centred in a hospital. The appointment would be by the local authority and would be full- or part-time. The Minister said there would be compensation for practices, but no details were given. The money invested in practices was between £50,000,000 and £100,000,000. This was dismissed in the Minister's proposals with small consideration. The *British Medical Journal* had said it almost looked as if the Government wished to claim absolute control of the general practitioner for strict supervision of certification by the doctor. The upshot of it all was that the medical profession turned down further discussion of the proposals as completely unfruitful. They demanded a Royal Commission, but after further consultation that was set aside. The negotiations up to date had done incalculable harm through the whole rank and file of the medical profession.

Dr. MORGAN said Dr. Russell Thomas's speech was the essence of medical stupidity. The present negotiations were non-committal and exploratory. The Minister depended too much on the B.M.A. and leant toward bureaucracy. The present medical system was no credit to this country. It was completely uncoordinated. He wanted the Minister to negotiate with other bodies, medical as well as lay; to have in mind the principle of no public finance without lay control; and that medical education should be brought within the purview of some authoritative body.

Discarded "for the Present"

Mr. ERNEST BROWN said they dealt with a gigantic national issue—a question of the whole administrative structure of a comprehensive health and hospital service. It included the relation between the municipal hospitals and the voluntary hospitals. In February the Government had announced its acceptance of Sir William Beveridge's Assumption B. That meant that it announced its decision to go ahead with the preparation of a comprehensive medical service for the whole country. There was need for speed, although there was no need for haste. Several major issues demanded decisions soon. The country would want to know what was to be done with the Emergency Medical and Hospital Service when the war came to an end. The Government also had a duty to the large body of medical men and especially young medical men now in the Forces and to their future. Whatever conclusions they came to they would need good will. They were now in the preliminary stage, in which he sounded representatives of the medical profession, the major local authorities, and the voluntary hospitals to find out how their minds ran on the various issues, and to put before them ideas of his own. They had not reached the main discussion stage, which would be followed by legislative proposals when the Government had come to its conclusions. The second stage he still desired to be one of full and open review of the subject both in Parliament and elsewhere among the organizations, professions, and persons likely to be affected, including many now serving in the Forces. For this stage discussion might be more fruitful if he put before the House an appreciation of the main issues which gave everyone something to bite on.

Dr. HADEN GUEST: Without commitment?

Mr. BROWN: Certainly, at that stage. That would be the stage at which they could find out the feelings of the general public, who were to be the patients of this service. The third stage was the introduction of draft legislation, when the Government would have to make up its mind what was the right and practicable measure to introduce to Parliament. Since February he had arranged with representatives of the medical profession and the voluntary hospitals to embark on the preliminary and informal exchange of ideas. The medical representatives consisted of a group of medical men and women brought together by the B.M.A. and the Royal Colleges. This Representative Committee agreed with him to discuss and exchange ideas in confidence and without commitment. The committee was not his appointment, but that of the profession. He had put a number of ideas to it, including some on a possible salaried basis for general practice in a comprehensive service. He invited the committee's own criticisms and counter-suggestions. After a number of meetings the committee suggested that the whole subject should be referred to a Royal Commission. They discussed the suggestion but agreed that the previous exchange of ideas should be resumed. Disproportionate attention had been directed to certain phrases such as that about the "discard." The committee had understood him to mean that if it would advance discussion he would discard for the present any ideas so far considered and would consider each further issue quite afresh. The discussions had been resumed. He was sure they would continue to be helpful. Fairly soon he hoped to publish a statement, perhaps as a White Paper, to afford a focus for all concerned. They ought not to take final decisions until the man-in-the-street and the individual doctor in practice or in the Forces had a full chance to consider the main issues fairly. He was amused to see it suggested that the Government intended to dragoon one of the oldest of the learned professions into a corps of "State lackeys," or to deny the ordinary individual the elementary right to have his say in choosing his medical adviser.

The House then adjourned for the Whitsuntide Recess.

Enemy Attacks on Hospital Ships

In the House of Commons recently Mr. A. V. Alexander, the First Lord of the Admiralty, circulated a list of hospital ships which had been sunk or damaged by the enemy, as follows:

1940:
May: *Atlantis*, off Norway, bombed four times, no damage.
,, *Brighton*, Dieppe Harbour, bombed three times, sunk
,, *Maid of Kent*, Dieppe Harbour, bombed, destroyed by fire
,, *St Andrew*, nr. Calais, shelled twice, no damage; nr. Dunkirk, bombed twice, no damage.
,, *St. Julien*, Dunkirk; off Calais and in Downs, shelled twice, bombed once, no damage; on passage to Dunkirk, bombed and machine-gunned, slight damage
,, *St. David*, off Gravelines, shelled from shore batteries, no damage; off Dunkirk, bombed, shelled, machine-gunned, no damage.
,, *Worthing*, off Calais, shelled twice, bombed once, no damage
,, *Isle of Guernsey*, off Calais, shelled from shore batteries, no damage; on passage to Dunkirk, bombed and machine-gunned, slight damage.
,, *Isle of Thanet*, off Calais, shelled from shore batteries, damaged; English Channel, bombed and machine-gunned, no damage
,, *Dinard*, off Dunkirk, shelled once, bombed once, slight damage.
June: *Worthing*, nr. Dunkirk, bombed and machine-gunned twice, severe damage.
,, *Paris*, on passage to Dunkirk, bombed three times, sunk.
1941:
Jan. and Feb.:
Dorsetshire, off Sollum, bombed once, machine-gunned once, no damage.
,, *Aba*, Tobruk Harbour, bombed, slight damage
April. *Aba*, Suda Bay, Crete (at anchor), bombed. slight damage.
May: *Aba*, Canea, Crete, machine-gunned, slight damage; on passage to Haifa, bombed twice, damaged.
April: *Vita*, Tobruk, bombed twice, damaged; on tow in Mediterranean, bombed, badly damaged.
,, *Ramb IV*, nr. Tobruk, bombed, slight damage.
Aug.: *Amra*, Gulf of Suez, torpedoed from aircraft, no damage
Sept. *Karapara*, Tobruk, bombed; damaged
,, *Dorsetshire*, Port Tewfik, bombed, slight damage.
Nov: *Llandovery Castle*, Suez (in dock), bombed, slight damage
Dec.: *Somersetshire*, between Tobruk and Alexandria, dive-bombed and machine-gunned, no damage.
1942
Jan: *Somersetshire*, between Tobruk and Alexandria, dive-bombed, no damage.
Feb: *Somersetshire*, Tobruk Harbour, bombed, no damage.
,, *Llandovery Castle*, between Alexandria and Tobruk, bombed three times, no damage.
Mar: *Llandovery Castle*, Tobruk Harbour, bombed, slight damage.
April: *Somersetshire*, between Alexandria and Tobruk, torpedoed, severe damage.
May *Ramb IV*, nr. Alexandria, bombed, sunk.

To this list must be added the *Centaur*, torpedoed and sunk a few weeks ago by the Japanese, with a loss of 268, including ten nurses, in addition to the matron, and, according to some reports, eighteen medical officers.

All these ships were properly marked in accordance with the Geneva Convention.

Investigations into Incidence of Tuberculosis

Mr. DOUGLAS on May 27 asked the Minister of Health whether any national survey had been undertaken to ascertain the effects of poor housing conditions and of malnutrition upon the incidence of tuberculosis. The MINISTER replied that reports were published before the war by the National Association for the Prevention of Tuberculosis on "Causal Factors in Tuberculosis" and "Tuberculosis and Social Conditions in England," and the association was at present conducting an inquiry into the relation between malnutrition and tuberculosis. The subject was also mentioned in the M.R.C. report issued in October last on "Tuberculosis in Wartime." Various lines of medical research were being officially pursued on the general question of nutrition, which might prove to throw some light on the particular question of the incidence of tuberculosis.

National Health Service Proposals

Mr. HOGG on June 3 asked whether the Minister of Health, in view of the misapprehensions resulting from his negotiations with the B.M.A. on his proposals for a National Health Service, would renew the Government's assurance that Assumption B of Sir William Beveridge's report still formed part of the Government's policy. Mr. BROWN: Yes, sir.

Medical Examination at Detention Barracks.—Sir JAMES GRIGG,* answering questions on May 18 about detention barracks, said regulations on the medical examination of soldiers sent to detention barracks were clear and explicit. A military court of inquiry would examine whether they were generally observed at Chatham detention barracks The medical officer of this barracks had been transferred elsewhere.

Increase in Short-term Sickness.—Mr. BROWN said on June 3 that there had been an increase in the incidence of short-term sickness among the insured population. He had no evidence to suggest that the increase was attributable to long hours of labour and to fatigue resulting from Civil Defence and Home Guard duties.

Notes in Brief

According to the latest figures in the Ministry of Health there are some 4,100 maternity beds in voluntary institutions, 8,000 in municipal homes and hospitals, and over 3,000 in the emergency maternity homes established by the Department, making a total of between 15,000 and 16,000 beds in England and Wales.

Of members of the Forces discharged owing to disability and whose claims for pensions have been rejected about 17% have been cases of psychoneurosis.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* during the week notifications of whooping-cough, diphtheria, and scarlet fever fell by 89, 82, and 76 respectively, but those of measles rose by 273.

Diphtheria was less prevalent throughout the country, a drop of 31 in Staffordshire being noteworthy. Scarlet fever was down by 32 in Yorks West Riding, 31 in Lancashire, and 31 in Staffordshire. Whooping-cough pursued a less steady course than diphtheria or scarlet fever, notifications being 71 fewer in Lancashire, 36 in Staffordshire, 29 in Warwickshire, and 28 in Middlesex; the largest rise was in London, 36.

Within the counties the largest increases for measles were in Monmouthshire 122, Oxfordshire 105, Essex 95, Lincolnshire 93, Northamptonshire 78, Somersetshire 71, and Glamorganshire 53. The biggest falls were in Norfolk 100 and London 64. This was the eighth consecutive week for which a decline has been recorded in London; the notifications have dropped from 1,166 to 365 during the period.

Additional cases in existing outbreaks accounted for a rise of 9 in the incidence of dysentery. In Warwickshire, Birmingham C.B., the cases rose from 3 to 23; in Gloucestershire, Bristol C.B., from 8 to 12; and in Cornwall, Bodmin M.B., from 3 to 9.

In *Scotland* scarlet fever notifications fell by 48, those for cerebrospinal fever rose by 10, the returns for Glasgow mounting from 5 to 14. An outbreak of dysentery has been reported from Edinburgh involving almost 100 cases, the majority being pupils and teachers at a school and residents in a university hostel.

Quarterly Returns for Northern Ireland

During the first quarter of 1943 the birth rate was 24.3 per 1,000, compared with an average of 19.7 for the five preceding first quarters. Infant mortality was 85 per 1,000 registered births and was 14 below the five-years average. The general death rate was 15.0 per 1,000 and was 1.1 below the rate for the March quarter of 1942 and 2.6 below the average rate for the first quarters of 1938-42. Deaths from pulmonary tuberculosis numbered 254 and other forms 86; the five-years average was 270 and 72. 231 deaths were attributed to the principal epidemic diseases, compared with 437 for the average of the preceding five first quarters.

The Week Ending June 12

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,966, whooping-cough 2,063, diphtheria 607, measles 6,724, acute pneumonia 637, cerebrospinal fever 50, dysentery 127, paratyphoid 6, typhoid 5.

No. 22

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 5.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county). (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

---

* Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

† Includes puerperal fever for England and Wales and Eire.

‡ Includes paratyphoid fever for England and Wales and London (administrative county).

§ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

The Services

Brigadier R. M. Luton, M.C., Canadian Army, was appointed C.B.E. (Military Division) in the Birthday Medical Honours.

Fl. Lieuts. G. D. Graham and N. Livingstone, R.A.F.V.R., have been appointed M.B.E. (Military Division).

Capt. J. W. Logan, R.A.M.C., has been awarded the D.S.O., and Capts. J. D Dow, E. J. Kerr, and Lieut. R. G. Boyd, R.A.M.C., have been awarded the M.C. in recognition of gallant and distinguished services in North Africa.

The following medical officers have been mentioned in dispatches: Group Capt. C. T. O'Neill, O.B.E., and Wing Cmdr. L. Freeman, R.A.F.; Squad. Ldrs. W. A. S. Falla, A. Wilson, R. G. D. Forward, R. G. Griffiths, W. Hopkins-Jones, Fl. Lieuts. O. T. Brown, N. G. Farrell, and A. Russell, R.A.F.V.R.

The *London Gazette* announces the appointment to O.B.E. (Civil Division) of Capt. (temp. Major) WILLIAM BRUCE KIRKLAND, M.B., B.S., Chief Medical Officer, Northern Territory Medical Service, Commonwealth of Australia. The announcement reads as follows: During the air raids on Darwin Dr. Kirkland was in charge of the hospital and was continuously on duty. In very difficult circumstances and with only broken equipment he remained for some weeks to deal with the air-raid casualties. After the first air raid many patients were successfully evacuated to safer accommodation. Dr Kirkland rendered outstanding services in conditions of grave danger.

CASUALTIES IN THE MEDICAL SERVICES

Prisoner of War.—Capt. H. A. Deverell, R.A.M.C.
Died.—Lieut.-Col. H. R. Pomroy, A.A.M.C.
Officially Reported Prisoner of War.—Surg. Lieut. A. P. Curtin, R.N.V.R.
Killed.—Surg. Lieut. J. H. Graves, R.N.V.R.
Reported Missing in North Africa.—Capt. I. E. W. Gilmour, R.A.M.C.
Prisoner of War in Japanese Hands.—Lieut.-Col. T. Hamilton, A.A.M.C.

Medical News

A joint meeting of the Nutrition Society and the Food Group (Society of Chemical Industry) will be held on Saturday, July 3, beginning at 11 a.m., at the London School of Hygiene and Tropical Medicine, when the subject of discussion will be "Milk." The chair will be taken by Prof. H. D. Kay, and papers will be read by Mr. J. L. Davies ("The Production, Supply, and Marketing of Milk"), Dr. A. T. R. Mattick ("Bacteriological Aspects of Milk Processing and Distribution"), and Dr. S. K. Kon ("The Chemical Composition and Nutritive Value of Milk and Milk Products"). The participants in the discussion will include Dr. W. R. Wooldridge, Prof. A. W. Ashby, and Prof. G. S. Wilson.

Under the auspices of the Association of Austrian Doctors in Great Britain Dr. A. Czech will give a lecture on "The Past and Future of Austrian Health Services," with lantern slides, on Thursday, July 1, at 6 p.m., in the Conway Hall, Red Lion Square, W.C.1. Guests will be welcomed.

Surgeon Rear-Admiral Cecil P. G. Wakeley will present a talking cinematograph film, illustrating first aid in the Navy, in the Council Chamber, the County Hall, West Street, Chichester, on Saturday, July 3, at 3 p.m.

The Derry Gardens, on the top of the well-known store of that name next to Kensington High Street Station, will be open on behalf of St. Bartholomew's Hospital from July 5 to 10 inclusive.

The trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee, they have agreed, if circumstances permit, to make the following awards for research in blood diseases, with special reference to leukaemia, in the academic year beginning on Oct. 1, 1943: grants for research expenses—Dr. J. Furth (New York), Dr. P. A. Gorer (London), Dr. A. H. T. Robb-Smith (Oxford), Prof. L. Doljanski (Jerusalem); part-time personal grant and grants for assistance and research expenses—Dr. W. Jacobson (Cambridge).

Official information has been received that Drs. W. Ainslie, R. E. Anderson, M. C. Bain, H. Allan, R. I. Macbeth, J. M. Sclater, and C. S. Wilson have been interned in Changi Camp, Singapore.

In the *Journal* of June 5 (p. 701) we printed an appeal for funds for a British Hospital to be built in Stalingrad. Since then medical men have sent in a number of donations, which now amount to £400. No donation is too small, and we hope that doctors will not hesitate to dip their hands into their pockets for an object so worthwhile.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Secretary of the Journal Board, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be sent to the Secretary.

TELEPHONE No.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London;* SECRETARY, *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh

ANY QUESTIONS?

Resistance to Tanning

Q.—*A man aged 26 is undergoing a course of artificial sunlight. He obstinately refuses to tan and is in consequence perpetually desquamating. He is dark-haired but has a very fair skin. I presume there is a marked lack of pigment which produces this state of affairs. I have had him on iron and the usual prophylactics against peeling, without any improvement. From a psychological point of view I should like him to obtain a good tan. I shall be grateful for any suggestions.*

A.—If the mercury vapour lamp is used a trial might be made of the carbon arc, or of the sun, the rays of which have a deeper penetration into the epidermis. The power of pigmentation if not naturally present cannot be provoked, and fair-skinned people require to be treated by artificial sunlight with caution. Desquamation is the sign of active response of the skin, and tanning the protective result.

Habitual Abortion

Q.—*A woman has had a series of spontaneous abortions and wishes to have a child. How should she be treated?*

A.—The treatment of so-called habitual abortion is largely empirical unless a cause can be found. General systemic disease—particularly nephritis and hypertension—and local pelvic disease—such as retroversion and malformations of the uterus—should be excluded. If no cause is apparent, a recent suggestion has been to have the blood of both husband and wife tested for incompatibility from the point of view of Rh factor. At present this is possible only at a few of the larger laboratories. Syphilis does not cause early abortions, but should be excluded if the abortions have occurred after the twentieth week of pregnancy.

Assuming that such investigations give negative results, then nothing further is necessary until the patient becomes pregnant again. She should be advised to defer pregnancy until six months after the last abortion and to report immediately one menstrual period is missed. No pelvic examination should then be made, but the diagnosis should be established by an Aschheim-Zondek test on the urine. This test may also give some indication of hormone imbalance such as gonadotrophic hormone deficiency. The patient should be instructed to live as quiet a life as possible, avoiding in particular riding in mechanically propelled vehicles, heavy work, and coitus. Various medical forms of treatment have been suggested from time to time, and although definite proof is lacking most clinicians are of the opinion that they have some value. The most commonly employed are progesterone, 2 mg. intramuscularly twice weekly up to the thirty-second week of pregnancy; thyroid, 1 gr nocte; and vitamin E, 6 mg. once or twice daily until term. These three can be combined with advantage and should be begun as early as possible in pregnancy. In place of progesterone, ethisterone, 5 mg. t.d.s. by mouth, can be given. It has a similar, if less powerful, action on the uterus. Finally, the patient should be assured of an adequate intake of iron, calcium, and vitamins A, B, C, and D. These are conveniently given in the form of a compound tablet

Antibody in Convalescent Measles Serum

Q.—*Is there any serological method for the estimation of antibody in convalescent measles serum?*

A.—There is none as yet. There is no doubt, of course, that, given a measles antigen, the serological assay of measles serum would be possible. But for a virus antigen to be satisfactory for these serological tests a high concentration of virus is essential. Blood or nasopharyngeal washings from cases of early measles, although virulent, would probably contain insufficient antigen to be of use as an antigen even in a complement-fixation test, which works with a lower "threshold" of antigen than agglutination or precipitation The recent claim to have cultivated measles virus on the chorio-allantoic membrane of the developing hen's egg has been confirmed, and this method should make available a suitable measles antigen for serological test.

Drug-resistant Organisms

Q.—*We often read that small doses of the sulphonamides are not only useless but may be harmful in producing a drug-fast strain of organism. Is there any evidence that this belief is a fact? In one of your annotations ("Prophylaxis of Rheumatic Fever," Journal, Dec. 19, 1942, p. 729) one might gather that small doses (1.0 and 1.3 g.) were found helpful over a period of years, and that objectionable results were few. In treating syphilis with N.A.B. some think massive therapy is much more dangerous than the relatively conservative doses extending over months or years. Are the instances comparable?*

A.—Continued exposure to sublethal concentrations of many types of antiseptic substance, ranging from phenol and mercury perchloride even, according to recent evidence, to penicillin, may produce increased resistance to its action. This is due not to a change in the metabolic behaviour of the bacterial cell but to the selective breeding-out of those individual cells which possess a greater capacity for resistance. There is both *in vitro* and clinical evidence that this is true of the sulphonamides, and the danger of inadequate dosage is well recognized, particularly in the treatment of pneumonia and gonorrhoea. The treatment of syphilis is not comparable for two main reasons. (1) Although drug-resistant syphilis occurs, there is no proof that a change in the spirochaete due to habituation to arsenical compounds is responsible for it; experimental attempts to produce this change have failed. (2) The extended treatment of syphilis does not consist in giving small doses of the drug three times a day, but in giving large doses at long intervals, following each of which the concentration in the body is high. Such a series of spaced attacks on the micro-organism, each adequate in itself, is quite a different thing from continuous under-dosage.

Vaccine in Pertussis Therapy

Q.—*Is pertussis vaccine of value in the treatment of whooping-cough?*

A.—The consensus in this country is unfavourable to the use of vaccines in the treatment of pertussis. When given in the paroxysmal stage they may even cause an increase in the frequency and severity of the spasms (Begg and Coveney[1]). In America, too, Sauer[2] could find no amelioration of symptoms in either mild or severe cases treated with vaccine. Yet Madsen states that Danish doctors are practically unanimous in claiming that treatment with vaccine will shorten the disease and render it much milder. Some support for this view is given by Thompson,[3] when, following treatment with pertussis "endotoxin," he observed amelioration and shortening of the infection in a group of *early* cases, but no effect among those in whom the disease was well established. His findings were well controlled. Claims have lately been made for the Lederle detoxicated pertussis antigen in the treatment of pertussis, but in a small series of hospital cases Baker[4] failed to confirm any beneficial effects. In summary, it is suggested that vaccine therapy with 0.1 to 0.2 c.cm. doses at 2- or 3-day intervals should not be discouraged in children intimately exposed or in the early catarrhal stage of pertussis.

Treatment of Gout

Q.—*What is the modern treatment of gout? Has the present-day patient any better prospects from a prognostic point of view than, say, his grandfather had?*

A.—The treatment of this acute condition has not changed, as reliance is still placed on colchicum. This is given in full doses of 15 minims of the tincture combined with 10 to 20 gr. of sodium salicylate and 20 gr. of sodium bicarbonate every 4 hours. This medicine should be kept in the house and given as soon as the joint begins to swell. The prognosis has greatly improved in the last 100 years, as various factors, like lead poisoning and septic foci, which are believed to favour attacks of gout, have been largely eliminated, and the preventive treatment is much improved. Various drugs—cinchophen, aspirin, and calcium aspirin—increase the output of uric acid in the urine. In a severe case 10 gr. of aspirin should be given 3 times a day 3 days each week until the joint has completely recovered. The dose should then be reduced to 2 days each week and later on to 1 a week. This dose may have to be continued indefinitely, or the dose may be reduced to once a month; but the patient should increase the dose as soon as he has any twinge of pain. If aspirin fails to prevent the attacks cinchophen should be used in the same way. It is more apt to cause unpleasant symptoms, like urticaria, nausea, or vomiting, and if these symptoms occur the patient should be told to stop taking it at once as he may develop a hepatitis and jaundice. Physiotherapy may be necessary to enable the joint to recover full movement. Patients should avoid sweetbreads, liver, kidneys, tripe, whitebait, sardines, sprats, and roes of all fishes; and red wines, champagne, and all malt liquors.

The National Bread

Q.—*What is added to wheat flour in the national bread? Is it more nutritious than the pre-war bread? And if calcium is added is this of any nutritive value?*

A.—During the past year several changes have been made in the ingredients of the national loaf. More English wheat is being used than a year ago, and at the present time it comprises 43.6% of the grist. Since Feb. 13 last, barley or a mixture of groats (dehulled oats) and barley has also been included. In May, 1942, calcium carbonate in the form of creta praeparata was added to the flour for the first time, at the rate of 7 oz. per sack of 280 lb., and at the end of April, 1943, approximately 89% of the national flour produced in the United Kingdom was so fortified. Since the middle of March, 1943, the addition of 2 lb. dried skimmed milk per sack has also been general, and over 90% of the flour is now fortified in this way. The chief difference that these additions have made is to the calcium. Pre-war white flour contained 16 mg. per 100 g.; unfortified national flour contained about 21 mg.; and the present flour with its calcium carbonate and skimmed milk contains 93 mg. The amount of calcium being added to the flour is just enough to combine with all the phytic acid in the bread and immobilize it, so that the calcium in the rest of the diet is available for absorption. It is unlikely that much of the calcium added to the bread is absorbed.

The present fortified national loaf is more nutritious than pre-war bread because it contains twice as much of vitamins B_1 and B_2, and a little animal protein from the added skimmed milk. It contains more iron, but it is still an open question whether this is available or not. It seems probable that it is present in the flour as the insoluble ferric phytate and is not absorbed.

"Morton's Metatarsalgia"

Q.—*Physical therapy having failed, will the symptoms of Morton's metatarsalgia continue indefinitely if untreated? Does operation provide a certain cure for this painful complaint?*

A.—Morton's metatarsalgia is not a diagnosis. Nevertheless in the majority of cases the underlying condition is an occupational strain. Physical therapy in all such lesions, though an important aid, is not often the fundamental method of approach. This requires careful search for and alleviation of the stresses to which the limb has been exposed; the removal of aggravating factors such as focal infection and other debilitating conditions; followed by the restoration of muscular control by re-education. The regulation of conditions of work and life, both physical and psychological, and attention to proper footwear, all are of importance. During the early stages of treatment relief to the metatarsal heads should be given by suitable pads applied directly to the feet, or by bars fixed to the soles of the shoes, immediately behind the metatarsal heads. Faradic foot-baths, graduated remedial exercises, etc., will then be more helpful in effecting a cure, which in chronic cases will often be hastened by manipulation under anaesthesia. No other operation should be necessary.

LETTERS, NOTES, ETC.

Sunlight and Desert Sores

Dr. W. J. BURNS SELKIRK (Birmingham) writes: Dr. Henderson (May 29, p. 657) may be interested in an observation by Dr. Eder, California. Children at his sanatorium subject to sunburn effects escaped these if given iron, though they were not anaemic (*Arch. Pediat.*, Dec., 1935, p. 833, quoted by *Med. Pr.*, Feb. 26, 1936).

A Spanish–English Medical Dictionary

Dr. M. G. MCELLIGOTT (Heathwood, Bushey Heath, Herts) writes to say that he has compiled a Spanish–English Medical Dictionary, which is now almost complete and of which the dedication has been accepted by an eminent Spanish surgeon. This work should fill a distinct need at the present time, but it awaits a publisher. Dr. McElligott would welcome any hints from Spanish-speaking readers which might make the dictionary more useful.

Welfare of Laboratory Animals

The Universities Federation for Animal Welfare (U.F.A.W.) is collecting information on: (1) anaesthesia of rats, rabbits, guinea-pigs, etc.; (2) methods of killing laboratory animals; and (3) living conditions, housing, diet, etc., of such animals. Views and suggestions should be sent to the Federation at its temporary address, 284, Regent's Park Road, N.3. A small panel of experienced persons will advise on the collected material. It is hoped that this pooling of the experience of those engaged in experiments on animals will enable the maximum of consideration to be given to the welfare of laboratory animals.

SUPPLEMENT TO THE

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 2 1943

MEDICAL PLANNING COMMISSION

VIEWS OF CONSTITUENT BODIES ON THE INTERIM REPORT

We publish below a summary of some views on the Interim Report of the Medical Planning Commission. It is hoped to publish an article in the SUPPLEMENT *each month on the work of the Commission.*

The bodies appointing to the Medical Planning Commission number 11. They include the British Medical Association, which took the initiative, the Royal Colleges and Royal Scottish Corporations, the Society of Medical Officers of Health, the Medical Women's Federation, the Faculty of Radiologists, and the Parliamentary Medical Committee. The 73 members of the Commission, however, have taken part in its work as individuals, and the appointing bodies are in no way committed to the interim report.

This fact makes the more interesting the observations of the various bodies, most of which have now submitted memoranda on the subject. On the "Questions for Decision" in the final section of the report, which were intended to focus attention on major points of principle, there is substantial agreement. The long debates at the Annual Representative Meeting of the B.M.A. last September and the much shorter debate at the Annual Conference of Local Medical and Panel Committees in November gave an indication of the mind of the general practitioners of the country. The Comitia of the Royal College of Physicians, the Council of the Royal College of Surgeons, and the executives of most of the other bodies have made in some cases extended commentary, especially on the parts of the report which deal with hospitals and with consultants and specialists, and it may be said that the plan as set out by the Commission for the co-ordination and integration of health services has been in broad outline approved.

Definitions and Basic Principles

Question 1.—The broad definition of the objects of medical service as set out in the first question is approved by all the bodies so far replying, except that two of them—the Royal College of Physicians of London and the Medical Women's Federation—demur to the phrase "positive health," and the Royal Faculty of Physicians and Surgeons, Glasgow, adds a third clause to the definition: "(*c*) to enable each individual thus provided with an adequate medical service to make his or her maximum contribution—spiritual, intellectual, and physical—to the life and well-being of the community."

Question 2.—All the bodies approve the principle of free choice of doctor and patient as an essential feature of any future service, although two introduce such a qualification as "where practicable," and the Royal College of Physicians calls for a limitation of panel lists. Some reservation as to free choice of consultants is mentioned by the Faculty of Radiologists.

Question 3.—Group practice is also generally favoured, but the Representative Body was anxious that it should not involve supervisory control in clinical matters, and that the group organization should not be imposed upon practitioners from the outside. On the other hand, the Royal College of Physicians, regarding group practice as synonymous with health centres, is of opinion that such centres should be provided by a statutory authority. The Royal College of Surgeons would restrict health centres to general practitioner services, holding that specialist services are the province of the hospital. The Royal College of Obstetricians and Gynaecologists strikes a cautious note. While describing the idea as revolutionary in British medicine, it is of opinion that health centres might be established in limited numbers as an experiment in carefully chosen areas. The Society of Medical Officers of Health agrees with the establishment of health centres, which it thinks should be provided and maintained by the local authority for both the preventive and curative sides of medicine. The whole-time staffing of such centres, however, can only be brought about gradually. In the transitional period the Society suggests that each local authority, after consultation with the local medical profession, should determine the methods of staffing most appropriate.

Question 4.—On the further question whether the provision of a medical service should be made by the Government for the whole community or for part of it only, it will be recalled that the Representative Body "went the whole hog" by the narrowest of majorities. On the other hand, the Annual Panel Conference expressed the view that the provision should be made only for persons compulsorily insured under the National Health Insurance Acts, with the dependants of such persons, and others of like economic status. The Royal Colleges of Physicians of London and of Edinburgh and the Royal Faculty at Glasgow favour provision for that section of the community within the income limit generally of National Health Insurance, and the Royal College of Obstetricians and Gynaecologists is of opinion that provision should be made for only a part of the community, but it is not prepared itself to draw the dividing line. The Medical Women's Federation reports much difference of opinion. The Faculty of Radiologists submits that the health services should be available to the whole community, but that any patient should be able at his own expense to employ the services of any doctor whose contractual obligations do not prevent him from rendering them. The contract under which practitioners work, the Faculty thinks, should be such that as many as possible are allowed to undertake private practice. The view of the Society of Medical Officers of Health is that all health services—hospital, medical, and allied—should be available to every member of the community without charge, with a chief medical officer in executive responsibility in each local government area. The services should be available to all who ask for them, and, within the organization provided, there should be maximum freedom of choice.

Central and Local Administration

Question 5.—A whole-time salaried Government medical service as the basis for the co-ordination and integration of health services was decisively rejected by the Annual Representative Meeting, and it has been turned down directly or by implication by most of the constituent bodies. The Society of Medical Officers of Health rejects a capitation or part-time salary basis in favour of a whole-time salary basis, which in its view has the dual advantages of administrative efficiency and the elimination of undesirable competition for patients, the conditions of all types of medical service to be determined by a suitable national body. The Socialist Medical Association, one of whose most able leaders is a member of the Commission, advocates that doctors and all other health workers should be employed as whole-time officers of an area council and appointed to the service of the area. A national salary and pension scheme would be instituted. The plan of proceeding by extension to dependants and others of the type of medical benefit available under National Health Insurance, but enlarged in scope, and making this the basis of the national health services does not appear to be favoured, unless a comment by the Royal College of Surgeons that medical services for the country should be built on existing foundations is taken as an endorsement.

Question 6.—Most of the bodies support, with certain modifications, the plan set out roughly in the interim report. This involves changes in central and local machinery, the setting up of medical advisory councils, the establishment of health centres where general medical work would be concentrated, the regionalization and unification of hospitals, the appointment of practitioners to a national service, presumably on a part-time salaried basis (with a variable element), compensation for loss of capital in a practice, and a gradual end to the buying and selling of practices.

The Representative Body preferred the central administrative machinery to take the form of a corporate body, as distinct from a Government Department in the usual sense, and referred the matter back to the Commission for further exploration. The Royal College of Physicians envisages a central body, predominantly medical in its composition, with executive and advisory functions, and established on a statutory basis. This would form a channel of communication between the Minister and the organized bodies of the profession. Local bodies might be set up after the same pattern. The Royal College of Surgeons holds that all health services should be directly under a single Minister, to whom a central medical advisory committee would have direct and regular access. The College has also certain specific proposals for local administration. The arrangement favoured for Scotland by the Royal College of Physicians of Edinburgh is a central medical authority under the Secretary of State with a predominantly medical committee to assist him, and, so far as local machinery is concerned, a council for each of the 5 regions into which Scotland should be divided. The Royal Faculty also favours regional governing boards constituted on an *ad hoc* basis.

The view of the Society of Medical Officers of Health is that the medical and health functions now distributed among several Government Departments should be brought together under one central Department, with health as its sole function and a Cabinet Minister as its responsible head, and that in local government areas, which should be enlarged to a suitable size, there should be a single authority for health purposes.

Hospitals and Consultants

On the subject of hospitals, their unification under a regional body is favoured by most of the councils or committees which have replied on the subject. The Representative Body urged the provision of beds for patients requiring nursing and medical attendance within the competence of the general practitioner, but not specialist investigation or treatment, such beds to be in the effective charge of the patient's own medical attendant. The Royal College of Physicians makes a number of recommendations: medical committees for all hospitals; methods of admission, except to teaching hospitals, to be co-ordinated; selection of senior staff by appointments boards with external assessors; adequate remuneration for all members of hospital staffs. The Royal College of Surgeons declares for the preservation of the voluntary hospital system, but would deny to patients with incomes above a certain limit admission to public wards.

All hospitals, voluntary and municipal, should be available for all members of the community on similar terms and conditions, according to the Society of Medical Officers of Health, and municipal hospitals should be included as teaching hospitals.

The Royal College of Physicians of Edinburgh also makes a series of recommendations: clinical posts in hospitals to carry salary and status no less than administrative posts; payment to members of medical staffs for services to persons coming in under the new scheme; appointment of members of medical staffs (other than to junior posts) by the regional authority on the advice of an appointments panel; all hospitals to be made available for the training of undergraduates. The Royal Faculty would give power to the regional boards to provide adequate accommodation for all cases requiring hospital treatment as well as diagnostic facilities for out-patients, to control the general finance of hospitals, and to co-operate in undergraduate and postgraduate teaching. Admission to hospitals and payment by patients for services rendered should be on a uniform basis throughout the region.

On the question of consultants, naturally, the Royal Colleges and Corporations have a good deal to say. The Royal College of Physicians would place consultants in three categories: whole-time with no private practice; whole-time with private practice in hospital only; part-time practice and part-time service in hospital. All these bodies are of opinion that the Royal Colleges might most suitably approve in some form or other the recognition of consultants and set up standards for consultant status, as well as conditions of service. The Royal College of Surgeons holds that specialists of consultant status should be more widely distributed, subject to adequate concentration in universities and other large centres.

The appointment of practitioners to the national service was the subject of several resolutions by the Representative Body, as, for instance, that all registered medical men and women should have a right to take part, that the conditions of service for men and women should be the same, together with a resolution affirming that satisfactory conditions of service were a necessary preliminary to acceptance of the scheme. The Medical Women's Federation believes that every practitioner should be eligible for appointment to the national service, and that there should be option so far as possible between whole-time and part-time service. Medical women should be given professional equality with men as regards opportunities, status, and remuneration, all appointments should be made with due regard to qualifications and efficiency, and there should be no discrimination merely on the grounds of sex or marriage. If the project of considering the family as a unit means that the same doctor must attend the whole family, the Federation disagrees.

The proposals relating to remuneration both of general practitioners and of consultants were referred back to the Commission by the Representative Body. Only two of the other bodies so far have mentioned the remuneration of general practitioners, and both of them—the Royal College of Physicians of Edinburgh and the Medical Women's Federation—approve the proposals in the report—namely, a part-time salaried basis, with some variation in proportion to the number of persons choosing a practitioner, also provision of pensions on retirement and provision for dependants on death of the practitioner.

Interim Changes

Question 7.—On the proposals for immediate post-war application, supposing the full adoption of the plan to be long delayed, all the bodies replying on the point approve some interim changes, with the exception of the Faculty of Radiologists, which considers that such changes would delay the adoption of the final scheme. The Representative Body was anxious that any interim changes should be so designed as to fit into the larger plan. The view of the Socialist Medical Association is that the Commission is unduly pessimistic in anticipating a long delay in initiating medical reform. Nevertheless, it calls for certain measures as of primary urgency—namely, the reconstruction of the Ministry of Health, to which should be transferred the civilian medical services in all their aspects; the reorganization of the Emergency Medical Service as a national service available to the whole population, without regard to local authority boundaries; co-ordination of hospitals; initiation of emergency domiciliary service as a means of organizing the work of general practitioners who remain in civil practice; direction of doctors into industrial medicine, and the encouragement of the supply of a greater number of doctors by a system of medical scholarships.

The two-way extension of National Health Insurance (to include dependants and others of like status, and to bring in consultant and specialist services) is approved by the Royal Colleges of Physicians of London and Edinburgh and by the Royal Faculty. The Medical Women's Federation feels that there should be no change in this respect while so many members of the profession are absent on service. The Representative Body passed no resolution on the subject, but the Panel Conference declared in favour of it. Other interim changes approved by all the bodies replying on this question included the setting up of regional hospital councils with executive or advisory functions and the establishment of experimental co-operative practice on voluntary lines.

The memoranda of the several of the bodies quoted, notably the statement of the Society of Medical Officers of Health, include many proposals and suggestions not strictly coming within the ambit of the seven questions, which will offer material for later comment.

A SCHEME FOR DIAGNOSTIC AND KEY HOSPITALS

BY

E. C. ATKINSON, M.B., B.S.

It would seem obvious that the building up of a more effective and efficient medical service for the future must start by improving the working conditions, the skill, and the status of the G.P. A State-controlled scheme in which the G.P.s exchange their practices for steady positions in health centres but suffer diminution of initiative, bureaucratic direction, and have no promise of materially better clinical opportunities, cannot improve their usefulness to the community.

The whole problem of increasing the efficiency of our medical service through the agency of the G.P. depends upon *maintaining* the standard of education and professional knowledge with which the G.P. is equipped when he leaves his teaching hospital and house appointments. This can only be done by affording him clinical opportunities and medical contacts such as he has been enjoying, but for the rest of his medical life. I say "maintained" because the scientific and clinical knowledge with which a newly qualified doctor leaves his house appointments should be sufficient for skilful conduct of general practice, provided he is given the opportunities to practise what he has learned. At present much of his learning becomes valueless through sheer lack of opportunity to exercise it. The existing system converts the majority of G.P.s into medical clerks, ushers, mere shop-walkers in specialists' stores. Unless the patient presents any but the simplest symptoms he is conveyed to a specialist department, left at the precincts, and not seen again until discharged.

What chance does this afford the G.P. of keeping up to date, or even of retaining the skill which he possessed on qualifying? His efforts to treat a number of his remaining patients are often so over-assisted by the public health organizations that he loses sight of what little interesting clinical material remains. Small wonder that after a time his diagnostic and therapeutic senses atrophy from disuse. Small wonder that specialists begin to doubt whether it is safe for him to pass a soft rubber catheter to relieve acute retention (*vide* recent correspondence in the *Journal*). And yet this is the man who, upon graduation, was patted on the back by the doyens of the profession, eulogized, and told: "Now you are a fully qualified medical practitioner; go into the world and prosper; you are the backbone of the profession."

All this is known, deplored, but left unremedied. Nor does the remedy seem to be forthcoming in the suggested plans of the interim report, as the limitation of G.P.s to health clinics with increased facilities for treatment of minor conditions still restrains them from instructive contact with interesting clinical material, which will go to key hospitals under exclusive specialist staffing and control.

Hospital Practice for the G.P.

The skeleton scheme suggested below of diagnostic and key hospitals would introduce all G.P.s into a hospital service providing them with the correct clinical material for postgraduate education without lowering the efficiency of that service. In many ways it is a cumbersome scheme, but that it is practicable and worthy of consideration is shown by the successful running in my district of a small hospital having many of the features of one of the hospital units described below. The scheme would work with but little difference in town or country. In country districts there would be a key hospital centrally situated, with the existing local hospitals as diagnostic units; in towns of large size it would sometimes be necessary to divide one big hospital into key and diagnostic sections.

Key Hospital.—This would be large and similar to the existing voluntary hospitals, staffed by specialists, and having all the usual departments and facilities. There would be house officers and a nurses' training school. Except in the case of teaching hospitals, patients would be admitted only on the written request of a doctor or upon transfer from a diagnostic hospital. There would be a far smaller out-patient department than usual, and out-patients would only attend for follow-up clinics and examination by special departments. None of the staff would engage in general practice.

Diagnostic Hospital

This would be a smaller institution altogether, with 100 or fewer beds according to the district. It would have public and private wards. There would be an *x*-ray diagnostic unit run by a radiographer, with a visiting radiologist, and a pathological unit in the charge of a technician directed by a visiting pathologist. Massage and electrotherapeutic units would be available for all patients, and, in industrial areas, there would be rehabilitation departments. Visiting consultants, who were junior members of the consulting staffs of the key hospitals, would attend regularly and constitute a supervising and advisory service to the hospital.

All the general practitioners in the district would be on the staff. They would admit their cases direct from their own practices. They would order all diagnostic procedures, without obtaining the leave of consultants, and when the diagnosis was complete the patient would be examined by the visiting consultant of the G.P.'s choice and the G.P. together. The consultant would advise, and if he agreed with the diagnosis would initial the case sheet, so that the patient would be (1) discharged, (2) transferred to a key hospital, or (3) retained at the diagnostic hospital for treatment. Surgical patients retained at the diagnostic hospital would receive treatment from the consultant, or from the G.P. if he had a surgical inclination. The amount of work deputed by the consultant to the G.P. would depend on the latter's ability. In medical cases the patient would be treated by the G.P. upon a plan agreed between him and the consultant and subject to a weekly review by the latter. Private patients would be solely in the G.P.'s care, and consultants would see them by invitation only.

The diagnostic hospital would in some instances receive back convalescent cases from the key hospitals to come under the care of the G.P.s who sent them. There would be an R.M.O. or senior student attached, who would carry out such duties as were allotted to him by the senior medical officer. Every year the G.P.s would select by voting one of their number to act as senior medical officer, who would direct the hospital policy, arrange the duties of the G.P.s, and act as superintendent. He would deputize for the consultant in his absence. The hospital would be run by a medical committee of the G.P.s.

The *x*-ray and pathological services would be available to the patients of the G.P. as out-patients, except for major procedures. Out-patients would not have to be seen by the consultant unless specially requested. For practical purposes the G.P.s' surgeries would be the out-patient department of the diagnostic hospital. Emergencies would be admitted to the diagnostic or key hospital direct according to the decision of the G.P. Practitioners not wishing to investigate their patients personally could admit them to the key hospital, or under the care of the R.M.O. at the diagnostic hospital. There could be frequent clinical meetings and demonstrations. G.P.s would be encouraged to develop specialties, and to act as clinical assistants at the key hospitals, to which they would always have admittance so that they might observe the progress of their patients. Those taking higher degrees would qualify for consideration for the junior consultant posts. Election to consultant position would be made by representatives of both key and diagnostic hospitals.

General Matters and Finance

All persons whose incomes qualified them for N.H.I. benefits would be admitted to the hospitals and to any out-patient treatment or investigation free of charge. Those with higher incomes would go into the private wards, and the total amount they would pay to hospital, consultant, and G.P. would be assessed by a committee investigating each case separately. All hospitals would be answerable to the State for their policies; they would be managed by their own committees otherwise.

Grants would be made by the Ministry of Health, which would draw funds from local taxation and the numerous societies into which insured persons pay their subscriptions. All consultants would be remunerated adequately for their hospital work, the salaries of the junior ones being sufficient to make them independent of private practice. G.P.s would be paid for their hospital services on the basis of the number of beds their patients occupied during the year. They would have their panels as before, health insurance having been extended to families of insured persons. They would be allowed private practice. The formation of central surgeries would be encouraged where the services, for example, of a nurse, dispenser, and secretary for medical notes could be shared, also certain equipment. G.P.s would draw the greater part of their remuneration from hospital and N.H.I. services.

Teaching hospitals would draw their patients from diagnostic hospitals, from G.P.s sending their patients direct, and from their own out-patient departments, which, for the benefit of students, would be run on a larger scale than in the key hospitals.

An Example in Cornwall

St. Michael's Hospital, Hayle, Cornwall, embodies many of the features of a diagnostic hospital with treatment facilities as already described. It contains just over 70 beds, and serves the districts of Hayle, Lelant, and St. Ives, and a large rural area; in all about 15,000 or more inhabitants in peacetime. There are 25 beds for males and 32 for females and 15 private rooms. There is a good diagnostic *x*-ray unit capable of all usual investigations. There is a modern, well-equipped massage and electrotherapeutic department providing short-wave diathermy, ionization, electric vapour baths, etc. The theatre is small, but well provided with all the apparatus found in a general hospital; there is a good sterilizing room. Pathological material is sent to the county pathologist, who charges a reduced fee.

The hospital is run and maintained by the lay and nursing Sisterhood of the Daughters of the Cross. Those not employed in nursing run the kitchen and laundry. One sister is a qualified doctor and acts as R.M.O., radiologist, and gives most of the anaesthetics. While certain G.P.s are on the permanent staff, any practitioner in the district can admit his patients, and either treat them himself or place them under the care of another doctor. As 4 of the active staff, of whom 3 are G.P.s, are Fellows of the Royal College of Surgeons there is no lack of specialist help. There is a visiting E.N.T. surgeon and a dental surgeon. A G.P. is at liberty to call in any specialist help that he considers desirable. There is a great spirit of co-operation among the members of the staff, and a complete absence of rivalry. Beds are allotted to patients and not to doctors. The Sister Superior is matron and controls the hospital. The ward sisters are all well qualified and the nursing is of a high standard. There is now a preliminary training school for nurses and no shortage of a good type of probationer. The nurses experience no difficulty in catering for the peculiarities of the several visiting doctors, and there appears to be no disadvantage in having more than the usual number of medical staff.

All the hospital's facilities are available to out-patients, but there is no out-patient department as such. All persons are admitted on their doctors' recommendations. There is no income limit, means test, or exhaustive inquiry by almoners. The word of the patient is accepted by the matron, and if the patient belongs to the H.S.A. the charges are covered, otherwise the charge is 2 gns., or as much of that as the patient can afford, or nothing. The private rooms are from 3 gns. to 5 gns.

The hospital has a rapid turnover of acute work. It has a very good reputation locally, and few people living in the district seek admission elsewhere, even for major procedures. The ready access to specialist help is a great attraction, and the knowledge that their G.P. will look after their immediate interests gives the patients confidence and banishes objection to the strange atmosphere of hospital. Through patients' gifts, payments, and allowances, the hospital is self-supporting and there is no existing debt.

To reproduce this hospital with additional improvements and alterations to bring it into line with the diagnostic hospitals would need State help at first. A lot would depend on the nursing staff, and the matron would have to be a very efficient and tactful woman, not only with administrative powers over the nursing staff, but vested with authority to act as hospital secretary and controller as at Hayle. Modifications would have to be introduced according to the locality, as, for example, special clinics in industrial areas for industrial injuries. As regards midwifery, each diagnostic hospital might have a small ward for straightforward cases where mothers who had no home facilities could be looked after by their own doctors under specialist supervision. Special hospitals — e.g., ophthalmic, E.N.T., and orthopaedic—might continue as they do now, but with much smaller out-patient departments and clinics; the routine procedure carried out at the clinics could be done by the G.P. at home. Public health organizations might assist in the administration of the hospital scheme, and their purely clinical personnel employed in preventive medicine. The child welfare, midwifery, and antenatal work could be undertaken by a rota of G.P.s at the diagnostic hospitals.

The three great advantages would be early diagnosis, better working conditions for the G.P., and greater readiness on the part of patients to enter hospital.

Correspondence

Free Choice of Doctor and Certification

SIR,—In the *Supplement* of Dec. 26 (p. 79) is an article by Dr. Buckley Sharp which seems to ask for criticism and challenge. It contains a number of assertions purporting to be statements of fact which are actually no more than the expressions of Dr. Buckley Sharp's opinion. He states: "Whenever a service is taken over, organized, and paid for by society as a whole (the State) the individuals lose their power to choose." This is surely not true. What the individual has lost is his power not to contribute. He is not under any compulsion to accept the service as ordered—e.g., he is still free to choose where his child shall go to school and may still be free to choose his doctor.

Then again: "The professional attributes most likely to lead to wide patronage and thus prosperity are an air of omniscience combined with a certain dogmatism, a sympathetic attitude to the patient and his complaints, and last, but not least, an uncritical readiness to issue certificates for the patient's material benefit." This is certainly not true. The doctor with a sympathetic attitude to the patient and his complaints, who knows his work, is easily able to be prosperous without either omniscience or dogmatism, and certainly without an uncritical readiness to issue certificates, etc.

Or yet again. "Hence the Workmen's Compensation Act has gained its title as a failed social experiment"; this is surely not more than Dr. Buckley Sharp's opinion.

Whether free choice, as we know it, will be a feature of the medical services of the future is and must be a matter for the public to decide. Doctors, after all, are much less interested in this than are the patients.

The main argument of Dr. Buckley Sharp's article on certification seems to rest on the assumption that the standard of honesty (or dishonesty) of the public and of the medical profession is such that neither together nor separately are they to be trusted to work a measure of greater social security. This, in my view, with a long experience of people and practice, is a false assumption. I suggest that the standard of honesty of the public and of the doctors is probably much the same. Experience tells me that for every person who would extend his period of incapacity improperly there are several who go back to work before they are really well. From this there emerges a standard of average honesty of both patients and doctors on which the success of any scheme of social security must depend. I have heard it stated that if every sick person drawing sickness benefit took one extra day of his benefit the scheme of National Health Insurance would become bankrupt. It is still very solvent.

In the social security scheme of Sir William Beveridge, when calculating the financial side, provision will require to be made for longer convalescence after illness. If the higher standard of health ("positive health") it envisages is to be attained no one must be allowed to return to work until health is properly restored. I suggest that anything up to a week may have to be added to the present experience of the average length of incapacity.

It is obvious that there is never in any illness an exact moment at which a patient is not fit to work and the next in which he is fit. It is a problem depending upon a number of factors beside the actual mental or physical condition of the patient, such as the nature of the work, the hours of work, distances to be travelled, etc. This has to be decided by the doctor and patient in honest agreement. Personally I am satisfied that the certification of incapacity can best be done by the patient's doctor as it is to-day. Dr. Buckley Sharp's fantastic suggestion that a second set of doctors—"certification doctors"—should be set up to examine the patient and to issue certificates of incapacity, following, I presume, the "treatment doctor" from house to house, is surely not meant seriously. Unfortunately it is always necessary to provide against dishonesty.—I am, etc.,

Birmingham. H. GUY DAIN.

The Ministry of Health has decided to remove the name of Dr J. J. Coghlan from the medical list of the Kingston-upon-Hull Insurance Committee as from Dec. 8, 1942.

REQUISITIONING OF CARS AND TYRES

In connexion with the recent census of laid-up cars, the B.M.A. has made the strongest representations to the Ministry of War Transport and the Ministry of Supply on the importance of doctors being allowed to retain their spare cars (with tyres) for emergency use and of doctors in the Services having a car (with tyres) available when they return to civil practice. The Ministry of War Transport has stated that if and when it is found necessary in the national interest to requisition laid-up cars from private owners, the Association's representations will be kept in mind Neither they nor the Ministry of Supply can give an assurance that in no circumstances will it be necessary to requisition cars or tyres belonging to doctors, but in no case will such cars or tyres be taken without the owner being notified and given an opportunity of appealing. The authorities concerned have been left in no doubt as to the serious consequences, especially in present circumstances, of a doctor being immobilized. Doctors are of course permitted, if they so desire, to keep two cars regularly in use, arranging for part of their petrol allowance to be allocated to the spare vehicle. This is the only method by which immunity from the risk of the second car (or its tyres) being requisitioned can be secured.

SUPPLEMENT TO THE

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 9 1943

MEDICAL STUDENTS IN CONFERENCE

VIEWS ON MEDICAL EDUCATION BY THOSE WHO ARE UNDERGOING IT

The British Medical Students' Association, which held its inaugural meeting last June, arranged a congress at B.M.A. House in London on Dec. 18 to 20, 1942. Nearly all the medical schools in the country were represented by an assembly of eager students, among whom there were many women, and the concise way in which they put forward their views and conducted their proceedings was a pattern to more senior gatherings.

Medical Students and National Service

At the opening session, which was presided over by Prof. A. V. Hill, F.R.S., an address was given by Mr. Ernest Brown, Minister of Health, who reviewed the position of medical students under the National Service (Armed Forces) Act. The reservation of male students, he said, was subject to periodical certification and satisfactory progress in their studies, and also to the performance of part-time service, though it was appreciated by the Ministry of Labour and National Service that students who had reached the clinical stage, and particularly those in their final year, might not be able to participate in such part-time service and could be recommended for exemption. Mr. Brown emphasized two points. If a student went to a university for his pre-medical studies, or was able to take them at a medical school, his acceptance must be completed before an enlistment notice was issued, but the procedure was usually of a routine nature. Secondly, periodical reports were furnished by vice-chancellors and deans on whether or not a student was making satisfactory progress.

The question of the opening of certain hospitals to women was under consideration by the Interdepartmental Committee on Medical Schools. With regard to the proposed increase in the quota of women in those hospitals already admitting them for the academic year 1942-3, the total quota for women was 308, and at present the acceptances had reached 323. The quota of the "mixed" schools was 1,036 (both sexes), and the acceptances for the present academic year numbered 916, so that there were still 120 vacancies for women students. The quota fixed for women might be exceeded to make up for a shortage of applicants within the men's quota. There was little opportunity for any immediate extension of existing facilities in teaching, which were affected by the absence of teachers on service as well as by the number of hospital beds and amount of laboratory accommodation.

At the conclusion of his address the Minister answered about forty questions put to him from the floor of the hall. He was asked his opinion with regard to a State Medical Service, and said in reply that he envisaged a comprehensive medical service such as was outlined in the Beveridge report.

Dr. Charles Hill, Deputy Secretary of the B.M.A., expressed a welcome from the Association, saying that it had no idea of interfering in the affairs of the student body, although it was available for help and advice, and the facilities of its house were at their disposal. The B.M.A. was anxious for a vigorous body of medical students because of the call for men and women of statesmanlike outlook in the future medical profession, especially when, as now, medical organization was on the eve of profound changes. He felt also that the stimulus for the recasting of medical education must in no small part come from medical students.

Reform of the Curriculum

Subsequent sessions were devoted to the consideration of a memorandum on medical education which had been prepared by a subcommittee of the association for submission both to the Medical Planning Commission and to the Interdepartmental Committee on Medical Schools set up by the Ministry of Health. All the medical schools in the country had been circularized, and the innumerable suggestions for the reform of the curriculum had been incorporated in so far as this was possible while preserving the coherence of the document. Some idea of the students' proposals may be gained from the summary of the suggested medical course:

School.
- Matriculation examination — including compulsory science.
- First year: General education in science, literature, economics, etc. Period of confirmation of choice of the profession.
- Second year: Travel, non-academic work, or remain at school, in which case take higher school certificate.

University or Medical School.
- First year: Pre-medical sciences and sociology. 1st M.B. examination.
- Second year: Pre-clinical sciences—anatomy and physiology, including histology, neurology, biochemistry, and pathology.
- Third year: As second year. 2nd M.B. examination.
- Next 33 months: Clinical studies; State qualifying examination.

The report was the subject of an animated debate, a long succession of students coming to the rostrum. Among the points made were the need for the wider use of municipal hospitals for teaching; the desirability of staff-student committees to discuss mutual difficulties; the benefits of a system of apprenticeship, if necessary compulsory, to general practitioners; the call for reservation of teachers; and the advantage of abolishing the long vacation and introducing a fourth term. One student thought that histology should be taught under physiology, being more interestingly assimilated under the general head of function than under that of structure. Another complained that the report mentioned sociology as a pre-medical subject, but did not recommend an examination upon it; he argued that if it were not made an examination subject little interest would be taken in it. Another wanted a more prominent place in the curriculum for industrial medicine, especially instruction in the chemicals used in the new industrial processes. Another criticized the shortness of the period—three months—allotted to clerking on a children's ward; in view of the fact that 40% of a general practitioner's patients were children, the period should be six months.

There was much debate on the admission of women. One student from Guy's expressed himself strongly against co-education in the medical schools, but the general feeling was in favour of it, and many men as well as women students urged that women should be admitted on exactly the same basis as men—not on an arbitrary method of selection, such as one woman to twenty men—and that women should have equality in respect of house appointments and postgraduate opportunities.

Away from Individualism

The closing address was given by Prof. J. A. Ryle, honorary president of the association. He declared that in the past the training and practice of members of the medical profession had been too individualistic. It had been directed too much to the intimate as opposed to the ultimate aspect of disease: to the tubercle bacillus rather than to the conditions under which tuberculosis continued to thrive. There had been too much separatism—of general practitioners from one another, of consultants from general practitioners, of hospital service from domiciliary service, of public health service from general practice, of research from all the rest. The student was also taught little about the subject of health though much about the departures from it. He had heard recently qualified men complain at the prospect of having to go into the R.A.M.C., because they would see no interesting cases. But on the contrary it would be a splendid opportunity to practise social medicine. It was a far greater function to be a battalion medical officer, keeping 800 men healthy, than to be a house-officer in charge of 40 beds, half of them filled with incurables. Prof. Ryle was heckled for over an hour at the close of his address.

Sir CHARLES WILSON addressed a private session of the Congress, and another session was devoted to discussing a programme for the association. A committee was set up to study the Beveridge report and to report to the next congress. Greetings were sent to students of Allied nations. The assembly passed a resolution whole-heartedly approving the acceleration of the medical curriculum in this time of national crisis, but approving also the maintenance of examination standards as recommended by the G.M.C. Other specific recommendations included the planned reservation of teachers in all medical schools, the greater use of women in teaching posts, the fullest possible use of all available hospital material in the vicinity of each medical school, and the setting up of efficiency committees covering lay and medical staffs and students with a view to improving hospital organization. The principle of equal admission of women was approved. A compliment should be paid to Mr. I. R. Clout (Westminster) and Mr. A. D. Bangham (University College), president and secretary respectively, on the way the congress was conducted.

HOSPITAL POLICY OF THE B.M.A.

A meeting of the Hospitals Committee of the B.M.A.—the first for more than a year—was held on December 8 under the chairmanship of Dr. Peter Macdonald. Mr. R. L. Newell of Manchester was elected, in his absence, chairman for the session, Dr. Macdonald not seeking re-election owing to his duties as chairman of the Representative Body. On the motion of Prof. Picken, Acting Chairman of Council, the committee placed on record its great appreciation of Dr. Macdonald's services in the chair for a period of more than 10 years. Dr. Macdonald said that his successor might have a more interesting period of office, for events in the hospital world were moving fast, but he could not have a pleasanter one than he had had himself, thanks to the good will of his colleagues and of "the two best secretaries in the country," Dr. Anderson and Dr. Hill.

The first matter to which the committee devoted attention was a hospital dispute which has arisen at a provincial town, where an endeavour has been made to deprive the visiting medical staff of membership of the committee of management. It was stated that the chairman of the committee and the secretary had arranged to visit the area on the following day to interview the management. The committee, which had before it all the correspondence that had taken place, approved the action of the secretariat and endorsed resolutions which had been passed by the Executive Committee.

A large part of the time of the meeting was occupied with a discussion on cottage hospitals in relation to the proposals of the Nuffield Trust. The matter had been raised by Dr. L. J. Picton of Cheshire, who attended the meeting by invitation. Dr. Picton said that in his opinion the Nuffield proposals for what might be called the de-grading of cottage hospitals threatened to destroy the work which those useful institutions were doing. In so doing they would also destroy the general practitioner who practised, as his plate proclaimed, as "physician and surgeon," and who in many cases carried out some excellent work, both emergency and routine major surgery. He gave an account of the excellent cottage hospitals of Cheshire and of the operations performed in them. A consulting surgeon was generally not available for emergency operations except in large centres. He was anxious that the cottage hospital should not be relegated to the position of a mere convalescent home, and that general practitioners should not become just surgical dressers to, perhaps, young consultants of less practical experience. One member of the committee said that the remark about non-availability of consultant surgeons did not apply in his own scattered rural area, where, although the county hospital was perhaps 25 or 30 miles away, the staff was always available day and night to go out to perform emergency operations.

The feeling of the committee, after hearing Dr. Picton's statement, was that no doubt his arguments applied with a great deal of force to Cheshire and to other parts of the country where cottage hospitals were well staffed by general practitioners of skill and experience, but that there were other districts where perhaps the cottage hospitals revealed a lower standard. The problem of the cottage hospital raised the whole question of rural institutional medicine and required decision, and it was agreed to refer the matter to the Institutional Committee of the Medical Planning Commission, with the suggestion that it might usefully co-opt Dr. Picton and perhaps others specially interested. Dr. Picton pointed out that the problem also concerned the General and Special Practice Committees of the Commission, having wide implications for rural practice in general.

The committee next considered a resolution of the Annual Representative Meeting concerning the principle that a committee of senior medical staff should be set up in all hospitals, with the medical superintendent as its chairman, through whom the resolutions of the committee should be transmitted to the hospital management. The hospitals in view were, of course, particularly council hospitals, where it has been considered that too much responsibility for internal administration is vested in the medical superintendent and too little in other members of the staff. In voluntary hospitals a medical staff committee is usually given full scope for initiative.

After a long discussion the committee, while fully endorsing the need for a committee of senior medical staff, found some difficulty concerning the position of medical superintendent in relation to it. It was felt that he must have the right to attend its meetings, whether he was a member of the committee or not; many matters which might otherwise require formal representation would in that way be resolved over the table. The point whether the medical superintendent should be chairman or not should be left to the discretion of each committee, but it was thought important that the committee should have the right of direct access, which would rarely need to be exercised, to the hospital management committee.

The principal remaining business was to consider a memorandum recently adopted by the Medical Superintendents Society on hospital planning and policy. Suggestions were made for revision or for greater clarity at certain points.

HOSPITAL REGIONALIZATION IN SCOTLAND

A Medical Planning Study Group was recently formed at a general meeting of the medical profession in Edinburgh, and as a result of six months' study it has put forward a memorandum on post-war hospital problems, particularly, of course, as they apply to Scotland. The view of the Study Group is that a co-ordinated hospital service should combine the best characteristics of the voluntary and of the local authority hospital. For example, in local authority hospitals the medical staff are paid, and there exists a regular system of payment by patients according to their means. In voluntary hospitals the medical staff have the inestimable opportunity of influencing directly and even determining the type and character of the work carried out. In the future hospital service these principles should be retained. The terms "voluntary" and "municipal," in the opinion of the Group, should disappear in favour of some such term as "regional."

The first of several recommendations is that the new hospitals built by the Government, and now administered by them as part of the Emergency Hospital Service, should be taken over and administered by regional health authorities established by a central authority. The number of regions in Scotland would be, conveniently, 5, and boards of management for these hospitals would be set up either through the agency of the regional authority or of the local authority within whose area the hospital is situated. On the regional controlling body all the interests concerned in different groups of hospitals—voluntary, local authority, and E.M.S.—should be represented adequately and with equity, with as little disturbance as possible of the immediate management of any hospital.

The Group suggests that the central authority, which would formulate national health policy and establish regional authorities, should be a corporate body, responsible in Scotland to the Secretary of State, and including, in addition to the Government representatives, representatives of hospital staffs, medical officers of health, general practitioners, and allied health services. Each regional health authority should consist of, say, 20 members: 7 from the medical profession, 6 from lay bodies (local authorities and boards of management), 1 from the nursing services, and 2 nominees of the Secretary of State, 2 of the Department of Health, and a chairman and secretary. In association with these authorities there should be a number of advisory councils, one of them a medical council consisting of all the medical members of the regional authority, and additional medical members from the hospital staffs and schools of the region, to make recommendations concerning appointments, schemes of research, and other matters. There would also be a regional medical bureau to arrange for admission of patients in conjunction with the general practitioners severally concerned, to organize regional transportation service, to review the needs of hospitals for special equipment, and so forth. The financial arrangements between voluntary hospitals and local authorities would be by allocation of moneys by the regional authority to the governing bodies and the local authorities according to the needs of their respective hospitals, as determined on the advice of an assessor. From the funds at its disposal the regional authority would be empowered to allocate sums for remuneration of medical staff, and the following scale is suggested: (1) Whole-time senior appointments, £2,000 to £2,500. (2) Part-time senior appointments pro rata, based on a full-time salary of £1,500 to £2,000. (3) Whole- and part-time appointments other than senior, pro rata, based on a full-time salary as follows: (*a*) assistant surgeons and physicians, etc., £1,000 to £1,500; (*b*) clinical assistants and tutors, £550 to £900. (4) Whole-time house appointments, with board, junior, £150 to £200; senior, £250 to £350. (5) Medical superintendents of key hospitals, £1,500 to £2,000, to be reduced pro rata when there are other emoluments.

It is added that all these figures are based on appointments carrying with them a pension graded according to years of service and to salary at time of retirement.

HEALTH PROPOSALS BY THE COMMUNIST PARTY

The Communist Party of Great Britain has issued a memorandum containing its proposals for health services. The proposals are not, however, of the radical and far-reaching character which is found in some other manifestos; the question of a State Medical Service is not mentioned, and the purpose of the memorandum is to urge an immediate increase of efficiency in health services in order to assist war production and to prepare for and assist the "second front." There must be, say the compilers, a drive to get all workers more "health-conscious," an improvement in wage and salary rates and in living and working conditions for health workers, especially nurses, and a wide extension of trade union organization throughout the health services. Workers are urged to take every opportunity of raising health questions in production committees, trades councils, trade union branches, and all sections of the Labour movement. In particular it is suggested that in all joint production committees and shop stewards and works committees, one or two workers, forming a "workers' health inspectorate," should be made responsible for knowing the Factory Acts and the rights of workers under them, for seeing that their respective committees discuss health matters, and that, when necessary, advice is obtained from the factory doctor, industrial nurse, or the welfare department.

Many suggestions are made for meeting the shortage of nurses, including better use of staff in all departments of hospitals; and an improvement in the living conditions of nurses. A 96-hour fortnight, exclusive of meal-times but inclusive of compulsory lectures, is regarded as the national maximum. While, naturally, the pamphlet has a strong trade-unionist bias, it acknowledges the services of the British Medical Association not only in securing adequate rates of pay and conditions of service for doctors but in shaping national policy on such questions as national health insurance, nutrition, treatment of industrial accidents, and physical education. With regard to general practitioners the memorandum says that in wartime many adjustments might be made between medical men in general practice and those employed in hospitals and in public services so as to fill up the gaps in medical man-power. By means of committees democratically elected from all the doctors within a given radius—if the B.M.A. organization or the Local Medical War Committee is not suitable—medical personnel could be directed to provide domiciliary services, to man the various local clinics, and to supply factory doctors, without overlapping and with the minimum of disturbance and travelling.

Correspondence

Free Choice of Doctor and Certification

SIR,—Insurance practitioners would, I am sure, have been highly amused at Dr. Sharp's description of medical practice if his remarks had been addressed to a purely medical audience. Unfortunately they will have reached a wider public, and some readers may have taken them seriously, though surely no one will accept the idea of the "super-certifiers."

As a member of a multiple partnership I can assure Dr. Sharp that when one member of the partnership is unavoidably absent his patients frequently leave the surgery and come again at the next session.

The professional attributes which Dr. Sharp thinks "most likely to lead to patronage and prosperity" are mostly wide of the mark. "A sympathetic attitude to the patient and his complaints" is, and must be, an essential factor in any sphere of practice. As for "an air of omniscience," that departed years ago; patients to-day want to know why. "An uncritical readiness to issue certificates"—what nonsense; a doctor who wishes to conduct a large practice and to command the respect necessary for the conduct of that practice must be critical in the issue of all certificates and firm in refusal of those for which there is no warrant. Weak knees cannot compete against a stout heart, nor complacency against honesty.—I am, etc.,

Birmingham. J. A. BROWN.

Industrial Medical Attendance

SIR,—The present emergency has called for an increased number of practitioners functioning as full-time or part-time industrial medical officers. Quite a large number of these men apparently have not the time to conform to the ethical rules and duties for industrial medical officers as laid down by the B.M.A., in that they are not giving emergency treatment in cases of industrial accident and subsequently referring the patient to his own doctor, but are providing follow-through treatment from first to last.

There are several factors concerned in this particular form of abrogation of the ethical rules as I see it: (*a*) There is a loss of N.H.I. benefit, as the employer does not stamp the card during a period of incapacity. This loss is provided against when the insured person receives his certificate of incapacity from his insurance practitioner. Incidentally the particulars of the accident are not entered on the medical card. (*b*) The individual is deprived of the opportunity of seeing his own doctor at the time of and after the accident. This could assume importance in a compensation claim. In the ordinary case the reverse procedure holds good: the patient in an industrial accident who is attended by his insurance practitioner is also immediately seen by a representative of the insurance company concerned. (*c*) Follow-through treatment could be construed in the case of part-time workers as utilizing the appointment to secure the individual as the medical officer's own patient.

Some officers are also assuming the onus of providing the necessary certificate of exemption from duty as required by the Ministry of Labour. Cogent reasons can exist why the medical officer finds it necessary to issue such a certificate, whereas the N.H.I. practitioner is free from any such obligation.—I am, etc.,

Tipton, Staffs. L. H. EUNSON.

Reinstatement in N.H.I. of Service Personnel

SIR,—The Minister of Health has again refused to grant a wartime increase in the insurance capitation fee, and it is obvious that this is part of a Government decision affecting salaries in general, and it would appear that it is a waste of time to pursue the matter further.

There is, however, another step which could reasonably be taken which would go a long way towards alleviating some of the financial difficulties of practitioners, and it surprises me that this has not been urged upon the Minister long ago. The step I suggest is the immediate reinstatement in insurance of all insured persons who have been removed through having "joined H.M. Forces." This large group of insured persons comprises almost exclusively the young and healthy section of the population who before the war required the minimum of medical attention, and who helped to pay for the older and more decrepit sections. The latter now constitute the entire panel, and that is why the amount of work required is out of all proportion to the remuneration.

I would further suggest that in return for this concession practitioners should assume responsibility for all Service personnel who happen to be on leave in their areas, thus saving the clerical work involved in claiming fees from the Services, and making it easier for men or women on leave to obtain any necessary treatment. If there are, say, 6,000,000 men and women in the Forces, the cost of this concession would be approximately £3,000,000 per annum, which would fall on the Service estimates, while half of this amount would return to the Exchequer in due course in the form of extra income tax. In this way the Minister could remove a constant feeling of grievance and obtain a more satisfied medical service without infringing the Government's decisions with regard to the stabilization of salaries.—I am, etc.,

Coventry D. MURRAY BLADON.

NIGHT MEDICAL SERVICE FOR LONDON

There have been reports from other areas of difficulty in obtaining the services of a doctor at night, but so far as London is concerned the Local Medical and Panel Committee has decided to establish a night medical service, which will provide for rosters of doctors who are prepared to answer night calls in their own neighbourhood. Briefly the details of the scheme are as follows: All practitioners in the London area are invited to join the service. They will be grouped, and the area they cover will depend upon the size of the group; but it will, if possible, be limited to 1 mile from the doctor's surgery. One or more members of the group will be on duty at a time during periods of about a week—e.g., in a group of 8 with 2 on duty at one time each member's duty period will be one week each month. Copies of the roster will be sent to members of the group and to organizations in the area likely to be affected, such as hospitals, etc. One member of each group will act as hon. secretary and be a member of the executive committee which will administer the service under the Panel Committee. As regards fees. members of the service will normally attend patients for each other, and it is presumed that the question of a fee will not arise. In other cases the doctor on duty will recover a fee from the patient or other appropriate source. Each doctor joining the service will be asked to pay an annual subscription of 5s. to defray costs.

The scheme has been carefully worked out and the details embodied in a circular letter which, with a copy of the rules of the service and a reply postcard, has been sent to every general practitioner in the Metropolitan area. This is a very real attempt to deal with a problem which has been accentuated by the war, and one which may well become worse as the war continues. It is hoped that London doctors will support this scheme and thus help to distribute fairly what is, perhaps, the most arduous part of a doctor's work. As has happened on many other occasions in this war, necessity has pointed the way to much-needed changes, and we note with interest that the secretary of the London Local Medical and Panel Committee, Dr. C. L. Batteson, hopes that the night medical service will not be a wartime measure only but will stay to be a boon to doctors after the war is over.

The Ministry of Supply, in a statement on the care of rubber, reminds car owners and drivers that excessive speed, overloading, incorrect inflation, misalignment, and braking are among the chief causes of a tyre failing to give maximum results. A private car should not be driven at more than 30 m.p.h., at which speed the rubber lost through wear is considered "normal" and not "wasted"; at 40 m.p.h. about 24% of the rubber lost is "wasted," and at 50 m.p.h. the waste figure is nearly double. Over- and under-inflation are equally bad for tyres, and the former will not compensate for overloading. Tyres should be examined regularly for cuts, embedded stones, etc., and should be submitted for replacement well before the fabric begins to show. Care in braking and attention to the alignment of the wheels are other ways of getting the best out of tyres, and doctors, whose cars are in such frequent use, are asked to give special attention to these points.

H.M. Forces Appointments

ARMY

Col. (Temp. Brig) R. B. Price, D.S.O., late R.A.M.C., having attained the age limit for retirement, is retained on the Active List, supernumerary to the establishment.

ROYAL ARMY MEDICAL CORPS

Lieut.-Col. (acting Col.) L. A. J. Graham, having attained the age for retirement, is retained on the Active List, supernumerary to the establishment

Major (Temp Lieut.-Col) T. S. Law to be Lieut.-Col

Capt. (Temp. Major) S. G. M. Lynch to be Major.

TERRITORIAL ARMY

Col. (Temp Brig) E. M Cowell, C.B., C.B.E., D.S.O., T.D., has been appointed Director of Medical Services, and has been granted the paid acting rank of Major-Gen

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Majors (Temp. Lieut.-Cols.) J. B Woodrow and F T. Boucher from temp. commissions, to be Lieuts., retaining the temp. rank of Lieut.-Col. and War Subs. Major.

Major C M. Row, from temp. commission, to be Lieut., retaining the temp rank of Major and War Subs. Capt

War Subs Capts B J. Wilton, K W. Powell, and N M Segal have relinquished their commissions on account of ill-health and are granted the rank of Capt.

Lieuts G. B Stanford and O. L. Lander have relinquished their commissions on acount of ill-health and retain their rank.

To be Lieuts: G. J. Clarke, H Richards, W H Greany, A Cruickshank, H D. Fairman, J. L D Roy, J W. Scharff, J. M Barnes, J. B Tucker, J. Beggs, H Ferguson, W. Gibson, E. D. Allen-Price, R M Campbell, A. A. Martin, H. A. Raeburn, W. G. Swann, S. I. Arahams, A. R Allardice, W. Anderson, J. F R Bentley, R. H. Bowie, O. M Brewster, W E Brigg, G. G. Browning, J K A. Burn, M M. Campbell, M. Coburn, B. U Coffey, W. J. E Darling, E. B. Dawe, J De Larcy, N G. Douglas, G. W. Downes, P. A. Eyre, J N M Fairley, J. D. Fisher, G. A. Fitzpatrick, J A S. Forman, M. F Gallop, C. B. J. Glausher, R G. B Gilbert, E C. E. Golden, F. M. Gordon, S W. Grant, D Gregory, H. J Hale, C. R S Jackson, C. H. Jellard, I. F. B Johnston, R. Johnston, G B Jones, O. V Jones, L. G Kiloh, R. King-Brown, H. S Klein, W H Leake, H. G. Letcher, H McK. McDonald, J C McDonald, D. Martin, R. Meek, J P. Mitchell, R. M. Moore, L. F. Pearson, J S S Pollock, A. Potellakhoff, T. M. Pollock, C M C. Potter, J. B Raper, D C. Robb, W G Roberts, D. F. Ross, C. A Simmons, G Skinner, B J. Smith, H. J C. C Smith, S. L Smith, R. G. Spicer, M A. Stanton, J F Stokes, M E. Tapisuer, G E Thomas, A. B. Tompkins, C H Watts, J H Wildman, R. B Wilson, W. D Wilson, A C. Woodmansey, J. V. Ryan (*correction*).

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C

The following M.O.s have been granted commissions in the rank of Lieut.: Ethel L. Deas, Jean C Nelson, Rona Price-Davies, Margaret I Ross, Mary A Saunders, Ellen G. O. Walsh, Gertrude A Willis.

ROYAL AIR FORCE

Wing Cmdr. R A G Elliott has resumed the rank of Group Capt on reverting to the retired list at his own request

ROYAL AIR FORCE VOLUNTEER RESERVE

H C Beccle to be Squad. Ldr (Emergency).

Fl Lieut. B. B. Botha has relinquished his commission on appointment to the S A M C

Fl Lieut F. T. Dodd has relinquished his commission on account of ill-health and retains the rank of Squad Ldr.

The notification concerning H. Avery in a *Supplement* to the *London Gazette* dated Nov. 24, 1942, p 5104, col 2, should have read Fl. Lieut and not Flying Officer

C. A. Lewis to be Fl. Lieut. (Emergency).

Flying Officers W B S. Crawford, J. W. Fleming, J. P Kelly, J. S Lane, W. M. Morgan, A. de W. Ranken, A. L. Alban, W. A. Glen, F. V A Bosc, W. Flynn, R. C Fuller, T Hardy, J. E Sharpley, D O. Wharton, R E. Dunn, G. H Boston, G. H. Cooper, A. Craig, A. Davis, J M Ferguson, A H. Hands, C. R. Sluming, M. L. Gaudin, T. B Russell, J. G Taylor, W. R. Barrington, R. U. Carr, J. F. Cartwright, W. T. S. McKean, P. G. McE G Jones, S. Gibson, A. A. Hill, P. H Bell, E. H B Hopkins, D. McCaw, R. W McDowell, Q St L. Myles, D Cowan, R. C Fraser, J. R. Slessor, A. Standeven, J M. Wilkin, J. L. Boyd, W. D Smith J E. Gilbert, M Gold, A R. Nettleton, A. D. McL. Douglas, and L Ross to be War Subs Fl. Lieuts

Flying Officer G B. Schofield has relinquished his commission on account of ill-health and retains his rank.

To be Flying Officers (Emergency): E. Barry-Smith, J. B. Pettigrew, R. A. Rutherford, J. S Boyd, D. W. F. Charlton, W. A. Clarke, J. R. Colville, J. H. Edgar, R. A. Moorehead, J. E. E Morgan, G. A. Powell-Tuck, G. Snowden, and B. McC Throne.

R.A.F.V.R.: DENTAL BRANCH

Flying Officer A G. Beaton, M.R.C.S., L.R.C.P., to be War Subs. Fl. Lieut.

A. T Wynne, M.B., Ch.B., to be Flying Officer (Emergency).

INDIAN MEDICAL SERVICE

Lieut.-Cols. S. L. Mitra and V. R. Mirajkar, O.B.E., have retired.

Capt. R. R. Prosser to be Major.

EMERGENCY COMMISSIONS

Lieuts (on probation) T. H S. Smith, F. Hunter, J A W. Bingham, M. J. Barry, C. Conway, J. W. Magner, C R. K. Carroll, F. A. H. Hall G. B. R. Walkey, N N Iovetz-Tereshchenko, R C. Hallam, G. Hannigan, H. V. Knight, S. E. Vincent, H. M I Davies, B. M Medley, T Stephens, A. J McG Cathro, W. E Owens, G. Quayle, D. Currie, J D Phibbs, C. G. R. Sell, A D A. Maconochie, W. J Aitken, A. M. Merriweather, A. Gray, I. L. H Hewlett, I D. Patterson, M. E. M. Fleming, and M. B. M. Blanden to be Capts. on probation.

POSTGRADUATE NEWS

A series of postgraduate lectures will be given in the West Medical Theatre of Edinburgh Royal Infirmary on Thursdays, Jan. 28, Feb. 4, 18, and 25, and March 4 and 11, at 4.30 p.m.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrics and Gynaecological Clinics and Operations *Daily*, 1 30 p.m., Post-mortems. *Mon.*, 2 p.m., Ear, Nose, and Throat Clinic. *Tues.*, 10 a.m., Paediatric Clinic; 11 a.m., Gynaecological Clinic; 2 p.m., Genito-urinary Clinic. *Wed.*, 11 30 a.m., Medical Conference. *Thurs.*, 2 p.m., Dermatological Clinic; 2.15 p.m., *X*-ray Demonstration on the Stomach by Dr. E J E. Topham *Fri.*, 12 15 p.m., Surgical Conference; 2 p.m., Gynaecological Conference; 2 p.m., Sterility Clinic.

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W—*London Homoeopathic Hospital*, Queen Square, W.C: Clinical surgery demonstration Wed afternoon (limited to 6). *National Heart Hospital*, Westmoreland Street, W.: Tues. and Wed., 10 a.m. Out-patient clinics.

DIARY OF SOCIETIES & LECTURES

ROYAL SOCIETY OF MEDICINE—*Tues.*, 2.30 p.m. Section of Pathology, at St. Mary's Hospital *Wed.*, 2 30 p.m. Section of Physical Medicine. *Fri.*, 3.30 p.m. Section of Obstetrics and Gynaecology; 4.45 p.m. Section of Radiology.

B.M.A.: Branch and Division Meetings to be Held

CITY DIVISION.—At Metropolitan Hospital, Kingsland Road, E., Tues., Jan. 12, 3 p.m., Dr. P Hamill: The Panel Pharmacopoeia and the Sulphonamides

GLASGOW AND WEST OF SCOTLAND BRANCH.—At Institution of Engineers and Shipbuilders in Scotland, 39, Elmbank Crescent, Glasgow, Tues., Jan 12, 3.30 p.m. Prof. J. M. Mackintosh: Nutrition and Medicine.

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue

MARRIAGE

GILCHRIST—STOCKTON.—On Jan. 2, 1943, at Dulwich, Norman S. Gilchrist, O.B.E., M.D., of 21, Harley Street, W 1, and 3, Alleyn Park, S.E.21, to Elizabeth Stockton, of 6, St. Mary's Mansions, W.2

DEATHS

ALLEN.—On Dec 28, 1942, at Letchworth, Frank James Allen, M.A., M.D., formerly Professor of Physiology, Mason University College, Birmingham, late of Cambridge and Shepton Mallet, in his 89th year.

BOYD.—At Craighouse, Beith, Ayrshire, on October 18, 1942, Robert Boyd, M.D., of 322, Great Western Street, Moss Side, Manchester, aged 69 years.

WYLIE.—On Jan 2, 1943, Dr. James Wardlaw Wylie, sometime of Mayville, Cleland, Lanarkshire, and late of Mora, Larbert Road, Bonnybridge, Stirlingshire.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JANUARY 16 1943

THE FUTURE OF THE COUNTRY'S MEDICAL SERVICES

BY
R. W. HARRIS
Chairman of the London Medical Service Sub-committee and sometime Assistant Secretary of the Ministry of Health

It was manifest from the outset that the labours of the Medical Planning Commission would not be restricted by its terms of reference, which were "to study wartime developments and their effect on the country's medical services both present and future." The Commission has proceeded to consider the whole question of the future of the medical services, whether as affected by wartime developments or otherwise. It is to be congratulated on an exceedingly interesting and well-balanced draft interim report, on the wisdom of publishing the report as a draft, and asking that it should be freely discussed by the profession. It is possible that the commentary of a layman—not without experience of administration—who has tried to keep himself informed of medical opinion over a period of years may be of some collateral value.

With the "broad definition of the objects of medical service in this country," as adopted by the Commission, there must be universal agreement. The differences of opinion begin when it is considered how the objects are to be attained.

The Case for Extension of N.H.I.

In paragraphs 47 and 48 of the draft report it is stated that the majority view is against a whole-time salaried Government service. It is contended that "the quality of individual service would not necessarily be improved by the replacement of a variable income by a fixed income or by the substitution of the State for the individual in the selection and employment of a doctor. . . . National Health Insurance has proved a greater success than was anticipated either by its supporters or by its opponents. . . . Its medical service contains features which have proved to be essentially sound, such as free choice of doctor, the minimum of interference by the State, and the central negotiation of terms and conditions of service."

As regards the question of the quality of the service being improved by the replacement of a variable income by a fixed income, it is surely unnecessary to say that no serious student of the subject has ever contended that an alteration in the method of remunerating the doctor would greatly affect the quality of the service which he gives. Has it not frequently been contended in support of the capitation system of payment under the N.H.I. scheme that a doctor will give as good a service when he is paid by a capitation fee as if paid a fee for each attendance or for each service rendered? But the question arises whether the objects of reform in medical practice as set out by the Commission are best attained and the best standard of medical service reached under a system of competition for patients, sale of practices, and all the financial troubles inherent in that system, particularly in the case of doctors wishing to establish themselves in practice. Criticisms offered by general practitioners themselves and summarized in the draft report form a grave indictment, but the gravity of the problem is by no means understated. The financial strain in many cases is becoming an increasingly serious menace to the efficiency of the medical practitioner.

Is it unfair to say that the medical profession has learned from industry the value of competition but has not to any large extent learned the value of organization? It is surely organization of medical practice which is necessary to procure the best results; the method of payment has not, or should not have, any real bearing on the question.

Employment of Doctor and Free Choice

The phrase "the substitution of the State for the individual in the selection and employment of a doctor" has about it a disarming air of rhetoric. Under the National Health Insurance scheme there is no selection of doctors for employment in the service; every registered practitioner can enter the service by signing his name, and it requires the operation of a very formidable piece of machinery to secure his removal.

It cannot be seriously thought by critics of any scheme of organized national medical service that any responsible body of persons is going to propose that the "State," through the agency of, let us say, the Civil Service Commission, is to select the men to be engaged in the medical service. The proposal which would command the most general assent would be that set out in para. 52 of the report, whereby a Central Medical Services Board "predominantly medical in its composition" would have "executive functions in regard to the entry of the profession into the service." The statement about selection of the doctor by the individual—as opposed to selection by the State—is difficult to understand, but it presumably refers to the free choice of doctor, which is, in theory, one of the cardinal features of service under the National Health Insurance scheme.

Is there not in this matter a wide difference between theory and practice? No one would deny the value of the principle stated on medical grounds; equally no informed person would assert that it is a vital factor under the National Health Insurance scheme with more than a small proportion of the patients. There is a constant change of population. Large numbers of people probably move every few years, and when they come into a fresh district they are faced with the choice of a fresh doctor. Is it seriously contended that any large proportion of them choose their doctor on any other grounds than proximity or the casual advice of a neighbour? Then, again, is not the recognition of the capital value of practices, so that they are bought and sold, in direct conflict with the idea that insured persons display any anxiety about the particular doctor who should attend them? It is not open to question that when a practice changes hands and the insured persons on the outgoing doctor's list are all notified they will automatically pass on to the list of the incoming doctor, unless they make a fresh choice; a quite insignificant number make such a fresh choice.

The right of a patient to choose his own doctor can be widely recognized under any scheme of national service, whether salaried or not, and there seems to be no inherent difficulty whatever in giving full play to the principle of free choice of doctor to the extent to which the choice is likely to be exercised. The experience of 30 years of insurance administration does not give any support to the view that a proportion of patients coming to a health centre would exercise the right of choice of doctor to such an extent as to create an embarrassment in the distribution of the patients among the doctors. At the outset, of course, there would have to be considered such questions as the right of the doctor coming under the scheme to bring with him, as it were, to the local centre his existing patients; indeed, this would be a common-sense beginning. If a doctor had an embarrassing number of patients, so that he would have an unfair share of the work, the difficulty could probably be met by informing the patients of the right they already enjoy to exercise a fresh choice. It may safely be predicted that the majority would have to be allocated, and naturally as many as possible would be left where they were.

Minimum of State Interference

There is always the danger of a certain amount of prejudice being introduced into these discussions by the use of the word "State," with its implications of State interference with the proper and normal functions of doctors and of a cast-iron discipline and control undermining the doctor's efficiency. These can be avoided at the outset of the establishment of a national service by the proper organization of the central and local administration, so that the medical profession has a clear and definite voice in those matters which affect the personnel and the quality and kind of the services to be rendered; and especially in the organization of the services at the health centres and with the content of those services.

Is the profession really satisfied with the present complications involved in having to deal with the title to benefit of an insured person and with the disciplinary machinery, even though it admittedly does not function to any large extent, this again being due very largely to the apathy of the insured persons?

Scope of a National Service

Those who press for the extension of the National Health Insurance medical service to the dependants of the present insured persons and to those of a "like economic status" often overlook the fact that the limit of £420 in the compulsory scheme is not a limit of total income, and that even as a limit of remuneration it does not apply to the great mass of the insured population—namely, those who are engaged in manual labour. The proposal bristles with such difficulties that it may well prove to be impracticable. Who is to decide? Are the income-tax authorities to come into the scheme? Can it be visualized what Parliament is likely to think of such a proposal?

And if an individual is held to be outside the scheme, is he to be debarred from the facilities afforded at the health centre, notwithstanding that as a taxpayer he has contributed to the cost? For in a national scheme, if gigantic complications and difficulties are to be avoided, there can be no datum line where people would cease to contribute towards the service. The health of the community is the first consideration of the community as a whole, and the time is not far distant when it will be recognized that everyone in the country must contribute to the service according to his ability to pay.

Would it be right or proper that one citizen should have some better kind of medical service than another, and is the citizen who is to be excluded from the benefits of the public service the one who, in fact, has made a larger contribution to the cost of the service than the citizen who is included? If the wealthy man has contributed to the medical service, according to his ability to pay he must clearly be granted the right, whether he wishes to avail himself of it or not, to all the facilities that are provided by the service.

Custom and tradition count for a great deal, and in a period of transition there must remain a large amount of private practice gradually and slowly dying; but if the same doctor is to take part-time salaried service under the national scheme based on a publicly provided centre, and concurrently carry on private practice from his surgery, confused and chaotic problems will persist. It would be idle to gloss over the fact that, however long the transitional period may be—and it may well prove to be much longer in consultant and specialist practice than in the case of the general practitioner—the days of private practice would eventually come to an end. For private practice would mean the right of a doctor and patient to come to an understanding as to the fees to be paid for a service for which the patient has already paid in full and which cannot be better than the best.

During the transitional period questions of compensation will have to be settled, probably in each individual case, by a court of arbitration. Parliament may well regard as worth while a generous scheme of compensation as part of the price of getting the best possible and most comprehensive service. This is not the place to examine the problems of the transitional period or the problems of compensation, but merely to recognize frankly that they are formidable. It is clear that a standing court of arbitration would have a long period of operations, dealing with individual cases in diminishing volume throughout the whole period of transition.

Central and Local Administration

With regard to administration, there should be whole-hearted approval for two statements in paras. 51 and 52 of the report. One central authority should be concerned solely with all the civilian medical and auxiliary services of the country, and this authority must be responsible through a Minister to Parliament. The Minister in the exercise of his powers would require, for the wider problems of administration (especially those relating to the co-ordination of the work of the various local authorities), a secretariat with the necessary financial, registration, and accounting arrangements; but the "Central Medical Services Board which is predominantly medical in its composition" which is visualized (although as an alternative to another scheme) in para. 52 is one that would command general assent. This Board, it is proposed, in addition to advising the Minister, would have "executive functions in regard to the entry of the profession into the public medical service, disciplinary machinery, superannuation arrangements, and possibly postgraduate and refresher course arrangements."

With regard to local centres of administration, the local authorities of this country as at present constituted are already greatly overworked, and it is the trend of modern legislation continually to add to their burdens. The proposal to link the existing public health services, including hospital administration, with the new public medical service would mean that the existing local authorities would have to be closely associated with or represented on any new authority that was established. But it does not seem open to question that new local authorities with large areas should be set up, and that in the schemes for establishing these authorities something like the counterpart locally of the Central Medical Services Board should be reproduced.

The questions relating to central and local administration are of the highest importance, but when the controlling authority has been decided upon, what really matters is the quality of the service ultimately provided at the local centres—that is the work of the practitioner himself. The controlling authority may be very efficient and wisely constituted, but it is the "delivery of the goods" by the individual doctor that matters. Parliament will decide, but will be guided very largely by those who will have to "deliver the goods."

Dr. J. H. Sequeira, F.R.C.P., F.R.C.S., well known in this country as physician in charge of the skin department of the London Hospital from 1903 to 1927, has recently returned from Kenya after a stay of 15 years. That he has taken an active part in the medical affairs of Kenya has been shown by the reports we have received and published from the Kenya Branch of the B.M.A. from time to time. He was president of the Branch in 1929 and 1933, and for 10 years edited the *East African Medical Journal*. He has also been consulting dermatologist to the East African Forces. The council of the Kenya Branch gave a farewell dinner for him early last year.

E.M.S.: PATHOLOGISTS' FEES

The scale of fees payable to pathologists at E.M.S. hospitals has been agreed with the Central Medical War Committee, and is the subject of the latest Ministry of Health circular (No. 2752) to county and county borough councils and other authorities with hospitals in the E.M.S. and all voluntary hospitals in the scheme. The following are the essential paragraphs from the circular.

Voluntary Hospitals on the Occupied-bed Basis

"2. A scale of fees, applicable only to Emergency Scheme work, has now been decided upon in agreement with the Central Medical War Committee. It will apply either where the pathologist is not in receipt of a whole-time salary or where, although receiving what is described as a full-time salary, he is not, at Dec. 31, 1942, precluded from undertaking pathological work for outside bodies or persons. The fee will be payable both for examining and reporting on specimens sent to the laboratory and where the pathologist makes an investigation and report upon a patient referred directly to him by an outside doctor. In the case of patients sent in the first place to a clinical specialist and subsequently referred by him to the pathologist, the proportion of the specialist's fee payable to the pathologist is a matter for local arrangement.

It has been agreed that the pathologist's fee shall be reckoned on the unit basis. The number of units to be computed for each investigation is shown on the Schedule to this circular. The maximum fee per unit is 1s. 6d., to include both professional fee and overhead expenses, but since there is much variation in the incidence of overhead expenses it has been decided to regard 1s. as the professional charge and 6d. as representing overhead expenses

As regards the professional charge, if more than one examination is carried out by a pathologist on the same patient the units will be aggregated subject to a maximum payment of one guinea.

3. *Financial Arrangements.*—The hospital should claim each month the full amount of 1s 6d. a unit and pay to the pathologist the specialist fee of 1s. a unit together with that part of the 6d. a unit agreed to be his share of overhead expenses. (The overhead expenses, as stated above, are reckoned at 6d. a unit, and if these are fully borne by the pathologist he may claim up to this amount from the hospital. When only part of the expenses is met by the pathologist the reimbursable amount will be reduced accordingly.) The claim on the Department should be in the form of a certified statement attached to Form E.M.S. 151A, setting out the number of investigations, the unit equivalent, and the amount claimed. The cases involved should be excluded from the number of out-patient attendances shown on the front of Form E.M.S. 151A or Form A.G., 136. If a retrospective claim is made under paragraph 4 it should be stated whether the out-patient attendances involved were excluded from the relative monthly returns.

The amounts claimed will normally be reimbursed monthly in full and final settlement. A sum equivalent to the hospital's own share, if any, of the 1s. 6d. units should therefore be excluded from Column (1) of Form A.G. 136. The form A.G. 136 will thus exclude pathological expenditure incurred in dealing with cases falling within the ambit of this circular.

4. The above-mentioned scale of fees will operate as regards pathologists in occupied-bed-basis hospitals as from Sept. 1, 1941, and claims for work done before that date

and not yet met can, if desired, be submitted on the unit basis.

Pathologists receiving Sessional Fees

5. It has been decided, with the concurrence of the Central Medical War Committee, to substitute the new scale for the sessional fees at present paid to pathologists on Class III contracts at hospitals other than those on the occupied-bed basis. The nature of the pathologist's work does not lend itself readily to the calculation of fees on a sessional basis, and it is felt that the charge per unit will be more appropriate. The pathologists concerned will be notified individually of the change in the method of remuneration. All work done by them on and after Jan. 1, 1943, in respect of patients under the Emergency Hospital Scheme, whether in respect of patients in the hospital or referred by outside doctors, will be chargeable on the new scale.

6. The pathologist will claim from the Department on the form which will be supplied—namely, at the rate of 1s. per unit—and will look to the hospital for payment of any sums in respect of overhead expenses borne by him. These payments will be made by the hospital out of the 6d. allowed for the purpose, which the hospital should claim from the Department. The claim should be made in the form of a certified statement as in paragraph 3 above, attached to Form E.M.S. 151A in the case of voluntary hospitals and to A.G. 138 in the case of municipal hospitals. A sum equivalent to the hospital's own share of the 6d. per unit should be excluded from Column 1 of A.G. 136 or Column 2 of A.G. 138 as the case may be."

Schedule

No.	Test	Units
1	Agglutination: for one antigen	3
	for each additional antigen	1
2	Blood, alkali reserve	6
3	,, Arneth count, ...	5
4	,, bilirubin, van den Bergh test, quantitative	4
5	,, calcium estimation	7
6	,, cell count, R.B.C. and haemoglobin	3
7	,, chloride estimation	4
8	,, cholesterin estimation	5
9	,, coagulation time	3
10	,, count (complete with differential film and haemoglobin estimation)	8
11	,, corpuscular and mean corpuscular volume	4
12	,, creatinine	5
13	,, culture	5
14	,, diastase estimation	5
15	,, fat estimation	7
16	,, film differential count only .	3
17	,, G.C. complement, deviation test ..	10
	For each additional serum ..	2
18	,, grouping (per blood)	1
19	,, haemoglobin estimation	1
20	,, Kahn test	2
21	,, for malaria or other parasites ..	4
22	,, matching for transfusion (per donor)	1
23	,, phosphatase estimation	15
24	,, phosphates estimation	6
25	,, plasma protein, total	7
26	,, platelet count	3
27	,, prothrombin index	4
28	,, red cell fragility test	5
29	,, reticulocyte count	3
30	,, sedimentation rate	3
31	,, sugar estimation	5
32	,, sugar tolerance (2½-hour curve), blood and urine tests	15
33	,, sulphanilamide concentration:	
	for first specimen	6
	for each additional specimen ..	3
34	,, urea estimation	5
35	,, uric acid estimation	6
36	,, Wassermann test .. .	10
37	,, white cell count only . ..	2
38	Cerebrospinal fluid, bacteriological, for T.B. Gram film and culture	5
39	,, ,, cell count, globulin, protein	3
40	,, ,, chloride estimation ..	2
41	,, ,, Lange gold curve, mastic, etc. . ..	4
42	,, ,, sugar estimation ..	5
43	,, ,, urea estimation ..	5
44	,, ,, Wassermann test (per fluid, one in a batch)	2
45	Calculi, qualitative chemical examination ..	5
46	Diphtheria, differentiation	6
47	Faeces, benzidine test for blood	1
48	,, culture for pathogenic bacteria ..	6
49	,, examination for T.B.	5
50	Faeces, microscopical exam. for ova, parasites, food residues	15
51	,, quantitative analysis of fats and fatty acids	15
52	Gastric contents, 1 sample, microscopical exam: acid and chloride estimations ..	4
53	Guinea-pig inoculation for T.B. and preliminary microscopy	10
54	Hair or scales for fungi	3
55	Pregnancy, Zondek-Aschheim or Friedman test for	10
56	Pus or fluid, Gram film only	2

Notes

1. An addition of two units is to be made to each complete examination when the patient comes to the laboratory or when the specimen is taken by the pathologist.

2. In the case of pathologists visiting patients at a distance, they should be paid the same mileage fees as are, or may be agreed upon for, other medical specialists.

DOCTORS' PETROL ALLOWANCES

In common with all other essential users of private cars, doctors are again to be called upon to effect economies in their use of petrol. Doctors' petrol allowances for professional purposes will be reduced by 10% for the 3-months period beginning Feb. 1, 1943, except in those cases where the reduction would result in an issue of less than 20 units, when the minimum allowance will be 20 units.

As a further necessary measure of economy, and in pursuance of the Government policy of discouraging the use of high-powered cars, allowances will be granted by Regional Petroleum Officers on the basis of a performance of not less than 20 miles per gallon, whatever the horse-power of the car. We are informed by the Ministry of Fuel and Power that during the year at least 400,000 cars of 12 h.p. or less have ceased to be licensed, so that there should be no appreciable difficulty in the way of changing cars of high h.p. for others that are less expensive of petrol. The Regional Petroleum Officer will give sympathetic consideration, however, to those cases where the continued use of high h.p. cars is clearly necessary, as, for example, for the regular transport of surgical equipment, or for a short period only while a change of cars is being arranged.

A reasonable saving in the consumption of petrol is the inescapable obligation of all petrol users at the present time, when increasing quantities have to be provided for the fighting Forces and replenishment of the nation's stocks becomes increasingly difficult. Doctors will, no doubt, examine most critically the use to which they put their cars with the objects of eliminating all unnecessary mileage and of contributing in full to the conservation of petrol. It is still the policy of the Ministry of Fuel and Power not to refuse petrol genuinely needed for essential medical work, and where a doctor can show, after a reasonable trial, that the reduction in his allowance will curtail his essential medical activities the Regional Petroleum Officer, in consultation with the Medical Liaison Officer, and, if necessary, the Local Medical War Committee, will make such restoration of the 10% cut as may be considered necessary in the public interest.

In the *Supplement* of May 23, 1942, we stated that a doctor who has established his claim for a given allowance will receive that amount in one lot, but it should be realized that the present general reduction will automatically reduce any previously agreed figure.

Correspondence

Free Choice of Doctor and Certification

SIR,—Dr. H. Guy Dain (*Supplement*, Jan. 2, p. 4) makes some comments and criticisms of my article on this subject which appeared in the previous issue. His first complaint is that a number of assertions made appear as statements of fact and are not prefaced in each case by the words, "in my opinion." Facts are for the most part no more than widely held opinions based on evidence that at the time appears to be conclusive; thus the facts of to-day may be untrue to-morrow (e.g., that the earth is flat). I cannot say how many share my views, but those who do appear to be numerous judging by my post-bag and other communications. The assertions complained of have been based on an extensive experience of the medical world from many angles. I was born and bred in a general practice. Since then, having worked in a considerable number of hospitals for a considerable number of years, I have been in frequent contact with many general practitioners, and for more than twenty years with the practical application of the Workmen's Compensation Act and with medical jurisprudence in general.

As regards free choice of doctor by patient for therapeutic purposes, I am entirely in favour provided there is a direct contract between the two. If medicine should become entirely or mainly a State-run social service with hospital treatment included, the preservation of free choice even at its present limited level is doubtful. It does not exist in the Services, and the analogy of schooling does not negative this prognostication. State-provided elementary education gives no choice to the vast majority and is compulsory, except for the minority who can afford to make their own private arrangements.

On the question of the attributes that lead to the greatest measure of patronage and thus of prosperity in medical practice, surely it is axiomatic that pure professional knowledge and skill play a minor role. To quote the memorandum of the Medical Practitioners' Union: "Patients like or dislike particular doctors for a great variety of reasons, most of which have very little to do with the skill which the doctor places at their service."

The description "failed social experiment" as applied to the Workmen's Compensation Act, as it has operated in practice up to the present time, is a quotation; and I am certainly not alone in so regarding it, judging by the amount that has been said and written on the subject.

I retract nothing of what I have said on certification. But Dr. Dain misinterprets my remarks into a general charge of dishonesty, disregarding the more subtle mechanisms of motivation. I maintain that doctors should not be put in the invidious position of having to give or withhold from their own clients certificates upon which the receipt of benefits from society depends. From inquiries I am satisfied that many practitioners would be glad to be relieved of this. An acquaintance in general practice has recently told me that the majority of those attending at his surgery nowadays call only to obtain some kind of war certificate, many being complete strangers to him. As a rule he issues the certificate demanded without undue hesitation, satisfying his mind with the thought that the Ministry of —— will not take much notice of it and also by refusing to accept a fee. In support of my thesis is the fact that the Ministry of Labour in consultation with the Ministry of Health has found it necessary to establish a system of independent medical referees to decide the merits of applications on medical grounds for release from scheduled employment or from taking up employment under direction in any case where a medical certificate submitted by the worker does not make it clear beyond all doubt that he is suffering from a specific illness or disability that clearly renders him unfit. Of course, frank dishonesty does occasionally come to light. Recently a hospital out-patient told me that he had had "six weeks' holiday on the panel" while admittedly in good health. Dr. Dain thinks that a satisfactory compromise is arrived at by there being several persons who return to work before they are really well for every one who would extend his period of incapacity improperly—i.e., two wrongs make a right. Surely we should aim at two "rights," even if it costs the public more. I am concerned with principle and not with cost; and the suggestion that the National Health Insurance scheme might become bankrupt if each sick person drawing benefit took one extra day of his benefit, though hard to credit, is irrelevant. Social service contributions are based on claims experience, and social service schemes are not in danger of being allowed to go bankrupt.—I am, etc.,

London, W.1. B. Buckley Sharp.

Sir,—Dr. Buckley Sharp (*Supplement*, Dec. 26, p. 79) describes an uncritical readiness to issue certificates as one of the attributes most likely to lead to prosperity. Dr. H. Guy Dain (*Supplement*, Jan. 2, p. 4) asserts that this is not true. May one ask Dr. Dain for a plain "yes" or "no" in answer to this question: All other things—competence, sympathy, and so on—being equal, is the doctor who is uncritically ready to issue certificates likely to prosper more than his colleague whose issue of certificates is rigidly guided by his knowledge that such certificates are cheques drawn upon other people's money?—I am, etc.,

Donald M. O'Connor.

Brenchley, Kent

Scheme for Diagnostic and Key Hospitals

Sir,—May I support the broad principles in the article on this subject (*Supplement*, Jan. 2, p. 2), and confirm their real practicability as in the example quoted. Personally, after some years in a London practice, where one's knowledge and skill were slowly diminishing from lack of facilities to join in hospital work, it was refreshing to find here such facilities, and the chance of adding to one's ability through them. Bureaucratic medicine and surgery appear today to aim at taking away from the G.P. more and more of the things which he "qualified" to do: to take them away not because he cannot do them properly, given facilities, but simply in order to give more work to "specialists." Such bureaucracy forgets that the higher the practical skill of the G.P. on the average, the better will be the health and happiness of the community.—I am, etc.,

Hayle. W. H. Palmer.

POSTGRADUATE NEWS

The Fellowship of Medicine announces Week-end course in rheumatism at Rheumatic Unit, St Stephen's Hospital (L C C), on Sat and Sun, Feb 27 and 28; revision course in anaesthetics, April 5 to 17, lectures daily at Royal Cancer Hospital, and practical demonstrations at various London hospitals.

WEEKLY POSTGRADUATE DIARY

British Postgraduate Medical School, Ducane Road, W—*Daily*, 10 a m to 4 p m, Medical Clinics, Surgical Clinics and Operations, Obstetrics and Gynaecological Clinics and Operations. *Daily*, 1 30 p m. Post-mortems *Mon.*, War Course on Special Problems in War Surgery begins; 2 p m., Ear, Nose and Throat Clinic. *Tues*, 10 a m, Paediatric Clinic; 11 a.m., Gynaecological Clinic; 2 p m, Genito-urinary Clinic. *Wed*, 11 30 a.m., Medical Conference. *Thurs*, 2 p m Dermatological Clinic; 2.15 p.m., *X*-ray Demonstration on the Duodenum and Small Intestine by Dr E J. E Topham. *Fri*, 12.15 p.m, Surgical Conference; 2 p m, Gynaecological Conference; 2 p m, Sterility Clinic.

Felllowship of Medicine, 1, Wimpole Street, W.—*London Homoeopathic Hospital:* Wed. afternoon (limited to 6), Clinical Surgery Demonstration *National Heart Hospital:* Tues. and Wed., 10 a m, Out-patient clinics.

DIARY OF SOCIETIES & LECTURES

Royal Society of Medicine.—*Tues.*, 4 p m General Meeting of Fellows. *Thurs.*, 2 p m. Section of Dermatology. *Fri.*, 2 30 p m. Section of Disease in Children; 2.30 p m. Section of Epidemiology and State Medicine. *Sat.* (Jan. 23), 10 a m., Section of Neurology, at National Hospital, Queen Square, W C.

Medical Society of London, 11, Chandos Street, W.—*Mon.*, 4 p m. Discussion: Defective Nutritional Deficiencies during Pregnancy and Lactation and the Influence on the Mother and Child, to be introduced by Prof. James Young and Dr. T. Izod Bennett.

B.M.A.: Diary of Central Meetings

February

3. Wed **Council**, 10 a m (*change of date*).

B.M.A.: Branch and Division Meetings to be Held

Perth Branch.—At Perth Royal Infirmary, Thurs, Jan. 21, 8 30 p m Dr W. D. Chambers: Psychopathic States.

Corrigendum.—In the summary of the views of constituent bodies on the report of the Medical Planning Commission in the *Supplement* of Jan. 2 the words "Royal College of Physicians" in the last line of column 1 should read "Royal College of Obstetricians and Gynaecologists" It was the latter body which called for a limitation of panel lists.

£29 11s. 7d.—Clackmannan (5th donation)

£20 7s. 6d.—Dumbarton County (8th donation).

Total—£47,936 13s. and £100 3½% Conversion Stock and £40 3% Defence Bonds

Cheques, payable to the Medical War Relief Fund, should be sent to Dr. G. C Anderson, Honorary Treasurer of the Fund, British Medical Association House, Tavistock Square, London, W C.1.

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTHS

Mackenzie Crooks—On Jan 4, 1943, to Gwy, wife of W/C L. Mackenzie Crooks, a brother for Elizabeth and David, at Red House, Wendover,

Milligan—On Jan 6, 1943, at Adlington Hall, Cheshire, to Margaret (*née* Ellis), wife of Capt. A. B. Milligan, R A M.C (over-seas), a son

Montgomerie—On Dec 13, 1942, at Bow Bells, Bawbrook, Shrewsbury, to Nora, wife of Major James Montgomerie, R A.M C, over-seas, the gift of a sister for Jamie.

Page—On Jan. 2, at Dunstall House Nursing Home, N W 3, to Margaret (*née* Moore White), wife of Lieutenant L G M. Page, R.A.M C., a son

Thompson—On Jan 5, 1943, to Dorothy, wife of Brian Connor Thompson, M.D., of 7, Marchwood Crescent, W 5, a daughter

Tomkinson.—On Dec 20, 1942, at Dorset House, Cheslyn Hay, Staffs, to Dr. Agnes Tomkinson (*née* Sutherland), wife of Dr. O. W. R Tomkinson, a daughter.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JANUARY 23 1943

MEDICAL WAR RELIEF FUND

THE SECOND YEAR'S WORK

The Medical War Relief Fund was established in Sept., 1940, for the assistance of British medical practitioners and their dependants who are temporarily in financial straits as a direct result of war conditions. The audited Statement of Account of the Fund for the twelve months ended Aug. 31, 1942, is published below. Although the greater part of the sum subscribed remains unspent, the committee hopes that the steady flow of subscriptions will continue, for it must be anticipated that the demands on the Fund will increase as the offensive phase of the war develops. Cheques, payable to the Medical War Relief Fund, should be sent to the Honorary Treasurer of the Fund at B.M.A. House, Tavistock Square, London, W.C.1.

Generous Contributions

The Committee of the Fund wishes to express sincere thanks for the continued support of many generous donors—individual medical practitioners and groups of practitioners, local units of the British Medical Association both at home and throughout the Empire, Local Medical and Panel Committees, and other medical societies and institutions. Subscriptions have come from doctors in every continent, from doctors confined in enemy prison camps, from doctors serving in His Majesty's ships on the high seas. The committee would refer in particular to the most generous help given by Australia and Canada, notwithstanding their own difficulties and anxieties. A final contribution from the profession in Australia brings the amount received through the Australian Federal Council of the B.M.A. to the magnificent total of approximately £A.4,500, while during the period under review nearly £1,400 has been transmitted from Canada through the Canadian Medical Association. Contributions have come from outside the Empire and from outside the medical profession. Grateful acknowledgment is made of a donation of £265 from the North Pacific Society of Internal Medicine, Seattle, and a donation of £250 from the Mufulira War Funds Committee, Northern Rhodesia.

Awards to Applicants

The amount distributed is somewhat less than during the first year, the decrease being attributable to the diminution in the number and severity of the air attacks on the home front. During the twelve months covered by this report thirty-six awards were made, including two awards to applicants who had previously received assistance from the Fund. The total amounts of the gifts and loans voted by the distribution subcommittee are shown in the financial statement below. Twenty-eight applicants received gifts, six were given loans, and in two cases both gifts and loans were awarded. The gifts vary in amount between £550 and £30, four exceeding £250 and thirteen exceeding £100. The highest amount granted as a loan is £220 and the lowest £22. The awards made between the date of the inauguration of the Fund and Aug. 31, 1942, amount to £13,029, the gifts totalling £8,967 and the loans £4,062, and the number of beneficiaries being seventy-three.

Acknowledgments

The Committee of the Fund wishes again to place on record its indebtedness to the Royal Medical Benevolent Fund for its valuable co-operation, particularly in the administration of awards payable in instalments over a period of months or years. Special thanks are due to Mr. E. C. Pennefather, secretary of the R.M.B.F., who has generously relinquished the honorarium voted to him as secretary of the distribution subcommittee and now gives his invaluable services wholly voluntarily. The committee acknowledges also with gratitude the help freely given by members of the staff of the B.M.A. and the generosity of the Association in providing accommodation for meetings.

Illustrative Cases

The following brief case summaries illustrate the variety of the circumstances which have resulted in appeals for assistance during the year.

Dr. N. had served at sea as a medical officer in the R.N.V.R. and had lost valuable medical equipment when his ship was bombed. On being invalided out of the Service he required help to re-establish himself in his considerably reduced practice, and he received a suitable gift for this purpose. Later he applied for, and was granted, a loan for the purchase of new apparatus.

Dr. O., a comparatively young widower, was killed during an air raid while on duty at a first-aid post, leaving two orphan children. His small practice realized a very modest sum. The children are being cared for by relatives whose income, supplemented by the small Government pension, is insufficient to provide suitably for their maintenance and education. The necessary help has been given in the form of a gift, payable in instalments over a period of years.

Dr. P. was a victim of a double raid on a cathedral city. The first raid ruined his house and the second destroyed his surgery and all its contents. He obtained other accommodation but needed assistance to enable him to pay for repairs, furniture, instruments, and drugs. The required amount was provided as a gift.

Mrs. Q. sailed under Japanese bombs from Singapore, where her husband was in civil practice. She had decided to remain with him, but was ordered to leave and could take few possessions with her. On arrival in England she lost no time in securing employment, but she was in need of a small loan, which was readily granted.

Mrs. R.'s husband held a public medical appointment in the Far East. When he retired on pension he did not return home but joined the R.A.M.C. in Malaya, where he was reported missing. Mrs. R. has obtained work that enables her to support herself, but the educational expenses of her son presented a problem which has been solved by a gift from the Fund.

Mrs. S. is unable to take up remunerative employment as she has a young child under her care. When her husband was killed while serving in the R.A.F. she was in no immediate difficulty apart from certain debts, only some of which were covered by a grant from the R.A.F. Benevolent Fund. The additional sum required was provided in the form of a gift.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

The following M.O.s have been granted commissions in the rank of Lieut.: Rachel P. Manchanda, Mary W. Bowen, Mary F. Brownlie, Mary H. Chadderton, Gertrude M. Child, Menna O. C. Jones, Margaret S. B. Langton, Bertha A. McDougall, Elizabeth M. F Tolmie, Dorothy K. Williams, Joan M. Cheale, Lorna M. M. Davies, Valerie M K. Davies, Mary B. Graham, Allison J. McNairn, Susan D. D. McMurray, Jean M. Markham, Eveline Moffett, Muriel L. Newhouse.

INDIAN MEDICAL SERVICE

Capts. F. C. Leach and R. D. Scriven, M.C., to be Majors.

EMERGENCY COMMISSIONS

Capt M. Seager has relinquished his commission on acount of ill-health.

The services of Lieut. D. J. Gilbert have been dispensed with on acount of ill-health.

To be Lieuts.. E. B. Weeks, J. W. Lusk, and Creina Shephered.

BRITISH MEDICAL ASSOCIATION

Physical Medicine Group Committee

The following have been elected members of the Physical Medicine Group Committee of the B.M A. for the three years 1943-6: Dr. J. Cowan (Stockport), Dr. C. B. Heald (London), Dr. G. Holmes (Matlock), Dr. P. Bauwens (London), Dr. C. W. Buckley (Buxton), Sir R. Stanton Woods (London).

Diary of Central Meetings

FEBRUARY

3 Wed. **Council**, 10 a.m. (*Change of date*)

POSTGRADUATE NEWS

The Medical Society for the Study of Venereal Diseases has arranged a series of general meetings to be held at 11, Chandos Street, W, on Saturdays, Jan. 30, Feb. 27, March 27, April 17, May 29, June 26, and July 24 (annual general meeting), at 2.30 p.m Details will be published in the Diary of Societies column of the *Supplement* for the appropriate weeks.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a m. to 4 p m., Medical Clinics, Surgical Clinics and Operations, Obstetrics and Gynaecological Clinics and Operations *Daily*, 1 30 p m, Post-mortems. *Mon.*, 2 p m., Ear, Nose, and Throat Clinic. *Tues.*, 10 a m, Paediatric Clinic; 11 a m., Gynaecological Clinic; 2 p m, Genito-urinary Clinic *Wed.*, 11 30 a m., Medical Conference; *Thurs.*, 2 p m., Dermatological Clinic; 2.15 p m., X-ray Demonstration on "The Colon" by Dr E J E. Topham. *Fri.*, 12 15 p m, Surgical Conference; 2 p.m, Gynaecological Conference; 2 p m., Sterility Clinic.

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W.—*London Homoeopathic Hospital:* Wed afternoon (limited to 6), Clinical Surgery Demonstration *National Heart Hospital:* Tues. and Wed., 10 a m, Out-patient Clinic.

EDINBURGH POSTGRADUATE LECTURES.—At Edinburgh Royal Infirmary, *Thurs.*, 4.30 p m. Prof. C. McNeil: The First Month of Life—the Scope and Significance of its Clinical Problems.

DIARY OF SOCIETIES & LECTURES

ROYAL SOCIETY OF MEDICINE.—*Mon.*, 4.15 p m Section of Odontology; 4.15 p m. Section of Medicine: *Thurs*, 4.30 p m Section of Urology

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, W.—*Sat.* (Jan. 30), 2.30 p.m., Major Paul Padget, U S. Army Medical Corps: Contact Investigation in Venereal Disease Control

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion to the current issue.

BIRTHS

BIRCH.—On Jan. 1, 1943, at Hillside Nursing Home, Faversham, to Diana, wife of Dr. R. G. Birch of Sittingbourne, Kent, a daughter (Diana Kathryn)

ROBINSON.—On Jan. 6, 1943, to Jo. (*née* Liddington), wife of Dr. H. D. Robinson, Great Missenden, Bucks, a son.

SEXTON.—At 35, Drumsheugh Gardens, Edinburgh, on Dec. 27, 1942, to Betty (*née* Cook), wife of Dr. J. P. Sexton, Colonial Medical Service (Nigeria), a son (John Michael)

Rubber Gloves.—The Ministry of Health (Circular 2740) states that for 1943 the maximum purchase of rubber gloves by a doctor will be 6 pairs. Booklets of six certificates, each certificate for 1 pair of gloves, will be issued, as last year, by the Central Medical War Committee. Applications for "supplementary rations" should continue to be made to the regional office of the Ministry of Health for the area in which the doctor lives; and should be accompanied by a statement of the grounds on which the application is made.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JANUARY 30 1943

Correspondence

National Ophthalmic Medical Service

SIR,—With the publication of the Beveridge Report the question of providing an efficient ophthalmic medical service for the whole of Britain as part of a national medical service open to all may become a leading one. Even if it does not, it is almost universally advocated that dental and ophthalmic benefits should be made statutory forthwith for the present insured population.

Although no definite data are available as to the actual number of patients to be treated annually for eye troubles of all kinds, including prescription of glasses, it has been asserted that there are not enough ophthalmic medical practitioners to cope with the work. I have contended for years that this is not so, provided there is proper distribution of practitioners throughout the country.

It is generally stated that in 1942 20,000,000 persons were entitled to the insurance medical service. It is a matter of common knowledge that about 10,000,000 of these get ophthalmic benefit. Though all pay the same contributions there is no uniformity or guarantee of the continuance of this or any other additional benefit, because of the reasons given in the Beveridge Report.

As all the Approved Societies are free to give any one or other of the benefits in part or in whole, it would be safe to conclude that on an average the societies spend at least 11s. 9d. per person who gets ophthalmic benefit. (According to Appendix G of the Beveridge Report (Cmd. 6405, p. 60) in the year 1940 the number of claims for ophthalmic benefit was 156,259, and the amount paid was £91,529 approximately, an average of 11s. 9d. per person.)

Again, according to the report for 1938 of the Chief Medical Officer of the Ministry of Health £449,000 was for ophthalmic benefit, and under the fifth valuation of Approved Societies the annual allocation for ophthalmic benefit is £630,000—i.e., for the 10,000,000 insured entitled to this benefit. Thus in the year 1943, for which the allocation is £630,000 at the rate of 11s. 9d. per person, over 1,000,000 individuals may get this benefit. Even if we work on the basis of at least 500 ophthalmic medical practitioners available for service, owing to the war, and if we take it that they will work 250 days in a year, each of them would have to attend 9 to 10 patients on each working day.

On the other hand, if the State decided to make this benefit uniform and statutory for the whole country (which could not be before 1945), it would give ample time for enlisting increased numbers of trained medical men and women on the B.M.A.'s approved list for this purpose. When the war is over most of the 1,000 ophthalmic medical practitioners on the existing B.M.A. list should be available for this work. If the Beveridge Report is adopted, and if we take 48,000,000 as the maximum population during and after 1945, then on the basis of 10% of the total population needing ophthalmic treatment we should have about 5,000,000 people to be attended to in each year. By that time—i.e., 1945-50—it should not be difficult to have 2,000 ophthalmic medical practitioners available for this work, and thus in each year the individual practitioner would have to attend 10 patients a working day, which surely cannot be too heavy a burden.—I am, etc.,

Doncaster M. D. THAKORE.

N.H.I. Disciplinary Machinery

SIR,—In an article on the future of the country's medical services (*Supplement*, Jan. 16, p. 9) Mr. R. W. Harris states that the disciplinary machinery does not function to any large extent, this being due very largely to the apathy of the insured persons. Unless one is inclined to split grammarian's hairs this can only mean that, in Mr. Harris's opinion, if the insured persons were not apathetic the machinery would function to a large extent. May I raise an indignant voice as an insurance practitioner at this statement? May I ask on what grounds Mr. Harris makes this remark? It seems to me that this statement, coming as it does from the chairman of the Medical Services Subcommittee, explains the feeling that comes to the unfortunate practitioner appearing before the committee that his case has been prejudged. It also explains the reason for the profession feeling that there is no one so disliked by the Ministry of Health as the insurance practitioner. May I also protest against this remark appearing without any editorial disclaimer as to agreement, in view of your circulation outside the profession?—I am, etc.,

London, S.W.1. A. HARBOUR.

The Beveridge Report

SIR,—The Beveridge Report is pointing the way to a State Medical Service for all in the near future, whatever political power holds sway in the post-war era. The medical profession must realize that the fate of medicine in this country is in the hands of the people and not in the hands of a few voluble committees or commissions, and the people applaud the Beveridge Report. Many of us, who are citizens as well as doctors, will welcome a clear-cut decision to sweep the slate clean of hypocrisy and myopic conservatism, and make a service for every citizen a reality. I have attended many a meeting in Pickwickian atmosphere, and listened to some earnest Tupman voicing his fears—loss of freedom and initiative, etc. But metabolizing mouthfuls until we are mouldy won't mould public opinion. We should acquaint the public with our ideas of a State service in the form of an attractive pamphlet, and the form of this pamphlet might well be a subject for a B.M.A. prize once we are agreed upon matters of remuneration, etc. Then, if and when the time comes to discuss terms with the Government, the public will be under no illusions as to what we doctors want if we are to function happily and efficiently, and not as disgruntled dupes. We have a great opportunity, but "time is not on our side." Sir William Beveridge has given us a warning.—I am, etc.,

Birmingham. A. WISEMAN.

CONDENSED MILK FOR INFANTS

Acting on the advice of the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council, the Ministry of Food has arranged for extra supplies of sweetened or unsweetened condensed milk to be available for (*a*) premature infants, and (*b*) infants who have had an operation on the mouth, throat, or gullet, or an abdominal operation not more than one month previously. Permits, which will be for a period of four weeks, will be issued by local food offices on application supported by a medical certificate. Those for premature infants will be renewable at four-weekly intervals on production of further medical certificates until the infant is six months old. For group (*b*) the permit will cover a period between the date of application and four weeks after the operation.

Applications for extra condensed milk for other children under six months will be considered individually by the Ministry's medical advisers, but each must be accompanied by a doctor's certificate giving details of the infant's condition, age, weight at birth and at time of application, and whether milk or any milk preparation other than condensed milk has been tried and found unsuitable. If applications are approved the permits will be for a period of four weeks, renewable on production of further medical certificates at four-weekly intervals until the child is six months old. When extra sweetened condensed milk is allowed the child's sugar ration, any authority to obtain National dried milk, and the priority allowance of liquid milk will be stopped for the relative period.

From Jan. 3, 1943, the following soap preparations will cease to be rationed if supplied against a doctor's prescription: *B.P.*—sapo animalis, sapo durus, and sapo mollis; *B.P.C.*—sapo kalinus, sp. saponatus, sp. saponis kalini, liq. saponis aethereus, liq. saponis antisepticus, liq. saponis olei cocois; and medicated soaps containing not less than 1% of mercuric iodide, not less than 4% of ichthyol, 2% of salicylic acid, 2% of resorcin, or 5% of sulphur.

H.M. Forces Appointments

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Capt. W. C. Cockburn has relinquished his commission on account of ill-health and has been granted the rank of Major.

War Subs. Capts. E Alderson, D.S.O., T.D., and J. A. A. Duncan have relinquished their commissions and have been granted the honorary rank of Major.

War Subs. Capts. J. P. Stallard, W. H. Peden, W. G. Tregea, and R. W. Bone have relinquished their commissions on account of ill-health and have been granted the rank of Capt.

Capt. J. G. T. Lunn to be Lieut., temporarily relinquishing the rank of Capt.

Lieuts. J E. H Griffiths and H. M. S. Stanley have relinquished their commissions on account of ill-health and retain their rank.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

War Subs Major W. E. Pycraft has relinquished his commission on account of ill-health and has been granted the rank of Major.

Supernumerary for service with Edinburgh University Senior Training Corps (Medical Unit): S. A Smith to be Lieut

ROYAL AIR FORCE

Air Commodores F C. Cowtan, A. E. Panter, and A. Grant, C.B.E., to be Air Vice-Marshals (Temp.).

B.M.A.: Branch and Division Meetings to be Held

NORTHERN IRELAND BRANCH.—Joint meeting with Ulster Medical Society at Queen's University, Belfast, Thurs., Feb. 4, 4.30 p.m. Short papers and demonstrations.

B.M.A.: Meetings of Branches and Divisions

ABERDEEN BRANCH: CITY OF ABERDEEN DIVISION

At a meeting of the City of Aberdeen Division, held at Aberdeen on December 10, 1942, with Dr. C. B. GRIEVE in the chair, Prof. JOHN GLAISTER gave an address on "Some Reflections on Medico-Legal Practice."

Prof. Glaister referred to forensic medicine as the "Cinderella" of medical teaching and to the poor recognition given to this subject in universities. He said the lack of facilities in the mortuary system in Britain for the standard of work required was a disgrace. Centralization—a chain system of suitable laboratories, necropsy theatres, etc., with modern equipment—was needed. The lot of a medico-legal witness was not an easy one. He had to be able to stand up to detailed cross-questioning by experts, and had no excuse for omissions, however inadequate the conditions under which he had to carry out his work. The training of lawyers in medical matters concerned with legal practice was very detailed. Police instruction also had reached a high standard. A very heavy onus was placed on the Crown to prove its case beyond all reasonable doubt. There were really very few unsolved mysteries; although the information never became public, there was police knowledge of the probable perpetrator of a crime, but it had been impossible to obtain the proof required to secure a conviction. Much criticism was offered by the "man in the street" on the expenditure of public money on legal cases, but a great deal depended on the unexpected in investigation. Circumstances did not lie but witnesses did, and a panel of jurists must have a completely open mind. It was unwise to attempt to put oneself in the position of the accused, as the psychology and mentality of accused persons were so different. In conclusion, Prof. Glaister showed lantern slides of the laboratory and microscopical examination of hairs and tissues.

The lecture was greatly appreciated, and on the proposal of Mr. A. C. MORRISON, Emeritus Professor of Conveyancing of the University of Aberdeen, a hearty vote of thanks was accorded to Prof. Glaister for his address.

B.M.A. LIBRARY

The following books were added to the library during October and November, 1942:

Ashman, R., and Hull, E: Essentials of Electrocardiography. Second edition. 1941.

Bertwistle, A. P: Descriptive Atlas of Radiographs. Fifth edition. 1942.

Boyce, F. F.: Role of the Liver in Surgery. 1941.

Cameron, A. T.: Textbook of Biochemistry. Sixth edition. 1942.

Conybeare, J. J.: Textbook of Medicine. Sixth edition. 1942.

Cyriax, J: Massage, Manipulation and Local Anaesthesia. 1941

Darlington, C. D, and La Cour, L. F.: Handling of Chromosomes. 1942.

Davies, H. M., and Coope, R.: War Injuries of the Chest. 1942.

Dobson, M.: Binocular Imbalance. 1942.

Eggleston, C.: Essentials of Prescription Writing Seventh edition. 1942.

Emerson, C. P., and Taylor, J. E.: Essentials of Medicine. Fourteenth edition. 1940.

Fairbrother, R. W.: Textbook of Bacteriology. Fourth edition. 1942.

POSTGRADUATE NEWS

The Fellowship of Medicine announces the following courses: Rheumatism, at Rheumatic Unit, St. Stephen's Hospital (L.C.C.), on Sat and Sun, Feb. 27 and 28, and revision course in anaesthetics at Radcliffe Infirmary, Oxford, March 15 to 26.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrics and Gynaecological Clinics and Operations. *Daily*, 1 30 p.m., Post-mortems. *Mon.*, Course on War Surgery of the Nervous System begins; 2 p.m., Ear, Nose, and Throat Clinic *Tues.*, 10 a.m., Paediatric Clinic; 11 a.m., Gynaecological Clinic; 2 p.m., Genito-urinary Clinic. *Wed.*, 11.30 a.m., Medical Conference; 2 p.m., Inflammation—2, Localization, by Prof. W. G. Barnard. *Thurs.*, 2 p.m., Dermatological Clinic; 2.15 p.m., *X*-ray Demonstration on Pneumonia and Bronchitis by Dr. E. J. E Topham. *Fri.*, 12.15 p.m., Surgical Conference; 2 p.m., Gynaecological Conference; 2 p.m., Sterility Clinic.

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W. —*London Homoeopathic Hospital*, Queen Square, W.C.—Wednesday afternoon, Clinical Surgery Demonstration (limited to 6). *National Heart Hospital*, Westmoreland Street, W.—Tues and Wed., 10 a.m., Out-patient Clinics.

EDINBURGH POSTGRADUATE LECTURES.—At Edinburgh Royal Infirmary, *Thurs.*, 4.30 p.m. Prof. J. R. Learmonth: Reflex Vasodilatation in Surgery.

DIARY OF SOCIETIES & LECTURES

ROYAL SOCIETY OF MEDICINE.—*Tues.*, 2 p.m., Section of Orthopaedics; 4 p.m., General meeting of Fellows. *Wed.*, 2 30 p.m., Section of History of Medicine; 2 30 p.m., Joint meeting of Sections of Surgery and of Urology. *Fri.*, 10.30 a.m. Section of Otology; 2.15 p.m, Section of Laryngology; 2.30 p.m., Section of Anaesthetics

ROYAL NATIONAL THROAT NOSE, AND EAR HOSPITAL, Gray's Inn Road, W C.—*Fri.*, 4 p.m. Mr N. Asherson. Acute Emergencies in Ear, Nose, and Throat

BIRTHS, MARRIAGES, & DEATHS

BIRTHS

MACDONALD.—On Jan. 14, 1943, at 34, Kimbolton Road, Bedford, to Joyce (*née* Walters), wife of Squad. Ldr. D. MacDonald, a son.

MAINGAY.—On Jan. 12, 1943, at Park House Nursing Home, Liverpool, 22, to Hope, wife of Surg. Lieut.-Cmdr. Hugh C. Maingay, R.N.V.R., a daughter.

MARRIAGE

CROSS—WHEELER.—On Jan. 11, 1943, at St Botolph's Church, Shenley, Flying Officer William George Cross, B D.S Lond., M.R.C.S, L.R.C.P., R.A.F.V.R, elder son of Mr. and Mrs W. M Cross, of Elstree, Herts, to Mary Lucy, elder daughter of the Reverend and Mrs. Wheeler, Shenley, Herts.

DEATHS

AINSCOW.—On Jan. 12, 1943, at his daughter's home, 152, Birmingham Road, Wylde Green, Warwickshire, James Allen Ainscow, M.D., D P H.

PARRY.—On Jan. 22, 1943, at 33, Wildcroft Manor, Putney Heath, London, S.W.15, Robert Henry Parry, F.R.C.S.Ed., late of Glasgow, aged 84.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY FEBRUARY 6 1943

BEVERIDGE REPORT: A PLAN FOR SOCIAL SECURITY

To help Study Groups we publish below those paragraphs from Sir William Beveridge's report on Social Insurance and Allied Services with which they are most concerned. The figures in parentheses denote the paragraphs in the report from which the extracts have been taken.

Guiding Principles (Paras. 6–10)

1. Any proposals for the future, while they should use to the full the experience gathered in the past, should not be restricted by consideration of sectional interests established in the obtaining of that experience.

2. Organization of social insurance should be treated as one part only of a comprehensive policy of social progress.

3. Social security must be achieved by co-operation between the State and the individual.

Summary of Plan (Paras. 17–19)

The main feature of the Plan for Social Security is a scheme of social insurance against interruption and destruction of earning power and for special expenditure arising at birth, marriage, or death. The scheme embodies six fundamental principles: flat rate of subsistence benefit; flat rate of contribution; unification of administrative responsibility; adequacy of benefit; comprehensiveness; and classification.

The main provisions of the plan may be summarized as follows:

The plan covers all citizens without upper income limit, but has regard to their different ways of life; it is a plan all-embracing in scope of persons and of needs, but is classified in application.

In relation to social-security the population falls into four main classes of working age and two others below and above working age respectively, as follows: (1) employees—that is, persons whose normal occupation is employment under contract of service; (2) others gainfully occupied, including employers, traders, and independent workers of all kinds; (3) housewives—that is, married women of working age; (4) others of working age not gainfully occupied; (5) below working age; (6) retired above working age. All classes will be covered for comprehensive medical treatment and rehabilitation.

Every person in Class 1, 2, or 4 will pay a single security contribution by a stamp on a single insurance document each week or combination of weeks. In Class 1 the employer also will contribute.

Medical treatment covering all requirements will be provided for all citizens by a national health service organized under the health departments, and post-medical rehabilitation treatment will be provided for all persons capable of profiting by it.

A Ministry of Social Security will be established, responsible for social insurance, national assistance and encouragement, and supervision of voluntary insurance, and will take over, so far as necessary for these purposes, the present work of other Government Departments and of local authorities in these fields.

Principal Changes Involved (Paras. 30–32)

All benefits will be obtainable by single weekly contribution on a single document.

Unification of social insurance and assistance in respect of administration in a Ministry of Social Security with local security offices within reach of all insured persons.

Supersession of the present system of approved societies giving unequal benefits for equal compulsory contributions.

Supersession of the present scheme of workmen's compensation, and inclusion of provision for industrial accident or disease within the unified social insurance scheme, subject to (*a*) a special method of meeting the cost of this provision, and (*b*) special pensions for prolonged disability and grants to dependants in cases of death due to such causes.

Separation of medical treatment from the administration of cash benefits, and the setting up of a comprehensive medical service for every citizen, covering all treatment and every form of disability under the supervision of the health departments.

Transfer to the Ministry of Social Security of the remaining functions of local authorities in respect of public assistance, other than treatment and services of an institutional character.

Transfer to the Ministry of Social Security of responsibility for the maintenance of blind persons, and the framing of a new scheme for maintenance and welfare by co-operation between the Ministry, local authorities, and voluntary agencies.

Ministry of Social Security and Local Authorities (Paras. 161–165)

The Poor Law, founded originally on the obligation of every parish to prevent destitution, was, until comparatively recently, the basic service for meeting need. But during the past 40 years there has been a strong trend away from the Poor Law and in favour of contributory State insurance and assistance administered on a national basis. The proposals in this Report (extending State insurance to new classes and new needs, raising rates of benefit, and prolonging the period of benefit) will considerably reduce the scope both of public assistance and of the Assistance Board. There can be no case for maintaining two or more large organizations performing precisely the same functions (payment of assistance according to needs) in respect of a reduced and declining number of recipients. It is therefore proposed that there should be one authority administering assistance on the basis of a uniform means test. It is essential to the logic and aims of the Plan of Social Security that this authority should be national and part of the Ministry of Social Security.

It is clear that the administration of the Ministry of Social Security must be decentralized, so that its local officers are in intimate touch with the problems and circumstances in their localities. This can be secured without making these officials servants of and subject to the control of the local authority. The present important function of the relieving officer of giving relief in cases of sudden and urgent necessity will in future have to be performed by the equivalent local officer of the Ministry of Social Security. There is no difficulty in practice in arranging for local administration by local officials of a central department. But to make such officials servants of the local authority means either that the local authority has discretion in spending money to which it does not contribute in any way and in which, therefore, it has no motive to economize, or that it has no discretion, in which case the local authority becomes an agent without responsibility. It is neither desirable for the strength of local democracy that local authorities should have to administer a service without discretion and according to detailed rules, nor compatible with a national minimum and a national Plan of Social Security that people should be given assistance according to a scale and conditions which vary from place to place.

The abolition of the Poor Law will still leave in the hands of local authorities the important and growing task of organizing and maintaining institutions of various kinds for treatment and welfare. In view of the increasing number of old persons there is probably considerable scope for experimentation with and development of services concerned with the recreation and welfare of the old, including special housing facilities. The domiciliary Poor Law Medical Service will presumably be merged into the comprehensive health service which is Assumption B of the Report, and in which local authorities will continue to play a very important part. Local authorities also will have a vital part to play in the other fields of social welfare, such as housing, education, and the recreative and cultural services. But these services will not be provided as part of the Poor Law. The Poor Law code will, it is proposed, be abolished. The many-sided activities of local authorities in relation to social security will be organized either as part of the different main social services, under the appropriate committees for public health, education, and so forth, or under a special social welfare committee concerned with or co-ordinating such cash-aid functions as rent rebates, or cheap or free school meals, to which a single means test would be applied.

The proposal in the Report, in accord with the views expressed by the English local authorities, is that responsibility for assistance should be transferred to the Ministry of Social Security, while provision for institutions will in general remain with the local authorities, who will be empowered to give cash payments which are incidental to institutional treatment. The precise dividing line and the details of the transfer, including the consequential financial adjustments, will have to be worked out in consultation with the local authorities. But one thing is clear: there will be need for continuous and friendly collaboration between the proposed Ministry of Social Security and the local authorities. Both central and local government have in their different ways a contribution to make to the future security and welfare of the people of this country.

Transfer of Functions to Ministry of Social Security (Paras. 171–175)

The precise form of departmental organization to be adopted for administration of social security cannot be determined finally without reference to the general organization of the work of the Government. There will clearly, however, be a considerable transfer of functions from other Departments to the proposed new Ministry of Social Security—e.g., (1) Assistance Board; (2) Customs and Excise Department: non-contributory pensions; (3) Ministry of Labour and National Service: unemployment benefit, employment services; the Ministry of Labour and National Service will continue to deal with labour questions generally, including training, for which it will provide institutions and post-medical rehabilitation. There must be co-operation between the Ministry of Social Security and Departments responsible for administration of the Mines- and Factory Acts and the prevention of accident and disease; (4) Ministry of Health: health insurance; (5) Home Office: workmen's compensation.

The Ministry of Social Security will not be responsible for medical treatment, which will fall within the sphere of the Health Departments, but there will be a joint committee of the Ministry of Social Security and of all Departments concerned in health and welfare for promotion of measures designed to prevent disease and reduce the burden on the Social Insurance Fund.

Estimate of Expenditure (Paras. 268–271)

The expenditure on health and rehabilitation services is estimated at £170,000,000 in 1945 and the same in 1965. The Report states that the figure given for the cost of the health and rehabilitation services is a very rough estimate requiring further examination. No change is made in this figure as from 1945 to 1965, it being assumed that there will actually be some development of the service, and as a consequence of this development a reduction in the number of cases requiring it. The estimate assumes that hospital treatment with all other treatment is included in the health service in virtue of the compulsory social insurance contribution—that is, without further voluntary contributions or charge on treatment; this proposal is subject to the further inquiry suggested in para. 437.

Taxation and Contributions (Paras. 272–280)

On the suggestion that social security should be financed only by taxation the Report says: "The suggestion is put, or can be put, in two alternative forms. One is that social security should be financed wholly from general taxation—that is, should become completely and formally non-contributory. The other is that social security should be financed by particular taxes assigned to this purpose. This suggestion in either of its forms breaks with the contributory principle, and logically, as is seen by some of its advocates, involves dropping the term "insurance." The advantages that can be claimed for the second form of this suggestion over the first form are that it maintains some connexion between paying and receiving, and may make it possible to widen the basis of taxation. It might, for instance, appear easier to reconcile wage-earners to income tax if the proceeds were earmarked for some purpose in which wage-earners had a personal interest, just as at one time a tax on petrol was introduced specifically to improve roads for the users of vehicles driven by petrol. But the arguments against assignment of taxes to particular purposes are strong; assignment is a method rightly unpopular with those who have responsibility for framing the general budget, and it is difficult to believe that it could prudently be applied to any part of a tax so fundamental as income tax. Moreover, as the experience of the Road Fund shows, there is no assurance that the earmarking of a tax to its original purposes will be respected. But it is unnecessary here to discuss the relative advantages or disadvantages of the two forms of the suggestion to abandon insurance contribution entirely in favour of taxation according to capacity. From the point of view adopted in this Report and advocated by the great majority of the organizations and persons who gave evidence to the committee, the suggestion involves a departure from existing practice for which there is neither need nor justification and which conflicts with the wishes and feelings of the British democracy. The scheme of social insurance which forms the centre of the Plan for Social Security is based on maintenance of the contributory principle—that is to say, of the principle that a material part of the total cost of maintaining income under the plan shall be met from moneys contributed by citizens as insured persons, on the basis of each individual paying the same contribution for the same rate of benefit. Contribution means that in their capacity as possible recipients of benefit the poorer man and the richer man are treated alike. Taxation means that the richer man, because of his capacity to pay, pays more for the general purposes of the community. These general purposes may, and in practice they must, include bearing a part of the cost of social security; if security is to be based on the contributory principle, they cannot include bearing the whole cost.

As regards division of the joint contribution in Class 1 between insured persons and their employers, the view taken here is that it is reasonable for the cost of unemployment, of disability other than that covered by industrial levy in industries scheduled as hazardous, and of retirement pensions and widowhood to be divided equally between the two parties, for employers to continue to make a contribution towards the cost of medical treatment for their employees, for the insured persons to be charged with funeral, marriage, and maternity grant and the bulk of the insurance contributions for medical treatment.

Social Policy (Para. 409)

Any plan for social security in the narrow sense assumes a concerted social policy in many fields, most of which it would be inappropriate to discuss in this Report. The plan proposed here involves three particular assumptions so closely related to it that brief discussion is essential for understanding of the plan itself. These are the assumptions of children's allowances, of comprehensive health and rehabilitation services, and of maintenance of employment. After these three assumptions have been examined, general questions are raised as to the practicability of taking freedom from want as an immediate post-war aim and as to the desirability of planning reconstruction of the social services even in war.

Health and Rehabilitation Services (Paras. 426–439)

426. The second of the three assumptions has two sides to it. It covers a national health service for prevention and for cure of disease and disability by medical treatment; it covers rehabilitation and fitting for employment by treatment, which will be both medical and post-medical. Administratively, realization of Assumption B on its two sides involves action both by the Departments concerned with health and by the Ministry of Labour and National Service. Exactly where the line should be drawn between the responsibilities of these Departments cannot, and need not, be settled now. For the purpose of the present Report the two sides are combined under one head, avoiding the need to distinguish accurately at this stage between medical and post-medical work. The case for regarding Assumption B as necessary for a satisfactory system of social security needs little emphasis. It is a logical corollary to the payment of high benefits in disability that determined efforts should be made by the State to reduce the number of cases for which benefit is needed. It is a logical corollary to the receipt of high benefits in disability that the individual should recognize the duty to be well and to co-operate in all steps which may lead to diagnosis of disease in early stages when it can be prevented. Disease and accidents must be paid for in any case, in lessened power of production and in idleness, if not directly by insurance benefits. One of the reasons why it is preferable to pay for disease and accident openly and directly in the form of insurance benefits rather than indirectly is that this emphasizes the cost and should give a stimulus to prevention. As to the methods of realizing Assumption B, the main problems naturally arise under the first head of medical treatment. Rehabilitation is a new field of remedial activity with great possibilities but requiring expenditure of a different order of magnitude from that involved in the medical treatment of the nation.

427. The first part of Assumption B is that a comprehensive national health service will ensure that for every citizen there is available whatever medical treatment he requires, in whatever form he requires it, domiciliary or institutional, general, specialist, or consultant, and will ensure also the provision of dental, ophthalmic, and surgical appliances, nursing and midwifery, and rehabilitation after accidents. Whether or not payment towards the cost of the health service is

included in the social insurance contribution, the service itself should (1) be organized, not by the Ministry concerned with social insurance, but by Departments responsible for the health of the people and for positive and preventive as well as curative measures; (2) be provided where needed without contribution conditions in any individual case.

Restoration of a sick person to health is a duty of the State and the sick person, prior to any other consideration. The assumption made here is in accord with the definition of the objects of medical service as proposed in the Draft Interim Report of the Medical Planning Commission of the British Medical Association: "(*a*) to provide a system of medical service directed towards the achievement of positive health, the prevention of disease, and the relief of sickness; (*b*) to render available to every individual all necessary medical services, both general and specialist, and both domiciliary and institutional."

428. Most of the problems of organization of such a service fall outside the scope of the Report. It is not necessary to express an opinion on such questions as free choice of doctor, group or individual practice, or the place of voluntary and public hospitals respectively in a national scheme. It is not necessary to express an opinion on the terms of service and remuneration of doctors of various kinds, of dentists, and of nurses, except in so far as these terms may affect the possibility of diminishing and controlling sickness and so may affect the finances of the Social Insurance Fund. Once it is accepted that the administration of medical treatment shall be lifted out of social insurance to become part of a comprehensive health service, the questions that remain for answer in this Report are, in the main, financial. Shall any part of the cost of treatment, and if so what part, be included in the compulsory insurance contribution? But, though that question is in itself financial, the answer to it may affect the organization of the service and may therefore depend in part upon views as to organization.

429. In dealing with this financial question it is desirable to consider separately domiciliary treatment, institutional treatment, special services like dental and ophthalmic treatment, and subsidiary services such as supply of medical or surgical appliances, nursing, and convalescent homes.

430. Domiciliary treatment is now paid for by persons subject to health insurance, for themselves by compulsory contributions, for dependants either by a charge for treatment when it is given, or, more rarely, by voluntary contribution through associations for public medical service. There is no obvious reason, apart from a desire to keep the insurance contribution as low as possible, why insured persons should be relieved of this burden wholly in order that they may bear it as tax-payers. If importance attaches to preserving the contributory principle for each benefit, it attaches also to contribution for medical treatment. There appears to be a case for including part of the cost of domiciliary treatment in the insurance contribution. This means that a proportion of the receipts of the Social Insurance Fund would be paid by the Fund to the Health Departments as a grant towards the cost of the medical service. The administration of this money would rest with the Health Departments.

431. But one consequence of this suggestion has to be noted. The Report proposes a compulsory social insurance scheme without income limits. Its contributing Classes 1, 2, and 4, though they pay different contributions according to the cash benefits for which they insure, are not income classes; each contains rich and poor. Any contribution for medical treatment must apply to all these classes, to every one in each of them, and must cover their dependants in Class 3 (housewives) and Class 5 (children). If a contribution for medical treatment is included in the insurance contribution, contributions will cover, not 90% of the population (the present insured persons and their dependants), as is assumed in the Draft Interim Report issued by the Medical Planning Commission, but 100% of the population. This will not, of itself, put an end to private practice. Those who have the desire and the means will be able to pay separately for private treatment, if the medical service is organized to provide that, as they may pay now for private schooling, though the public education system is available for all. But no one will be compelled to pay separately. The possible scope of private general practice will be so restricted that it may not appear worth while to preserve it. If, therefore, it is desired to preserve a substantial scope for private practice and to restrict the right to service without a charge on treatment to persons below a certain income limit, it will not be possible to include a payment for medical service in an insurance contribution which all are required to pay irrespective of income.

432. Institutional treatment is not included in the present health insurance contribution except to a small extent as an additional benefit. It is obtainable by any citizen in a public hospital subject to recovery of the cost—that is to say, to payment according to his means, or free if he has no means. It is obtainable in a private hospital, as a rule, either in virtue of previous voluntary contribution through a hospital contributory scheme, or on payment according to means as agreed with the hospital almoner. The growth of hospital contributory schemes in the years just before this war has been remarkable. They are stated to cover now more than 10,000,000 wage-earners, and they produce more than £6,500,000 a year for the voluntary hospitals; the cost of collecting this money is put at about 6%; in London and some other parts of the country contribution to a hospital saving association qualifies the contributor for free treatment either in a voluntary hospital or in a public hospital as may best suit his case. The Ministry of Labour Family Budgets in 1937-8 showed an average payment to hospital saving associations of 3½d. a week in every industrial household and 3d. a week in every agricultural household. British people are clearly ready and able to pay contributions for institutional treatment. Should a payment for this purpose be included in the compulsory insurance contribution and be passed on as a grant from the Social Insurance Fund to the Health Departments towards the maintenance of the institutions? The answer to this financial question, like the answer to the similar question as to domiciliary treatment, involves problems of organization as well as finance. If a payment for institutional treatment is included in the compulsory insurance contribution, there will be little or nothing left for which people can be asked to contribute voluntarily, and an important financial resource of the voluntary hospitals will come to an end. It will then be for the Health Departments to use the grant that they will receive from the Social Insurance Fund in whatever way best fits their hospital policy. If it is not included, people of limited means will have the choice, as at present, of contributing voluntarily beforehand or of paying at the time of treatment according to means.

433. The main considerations relevant to the choice between these alternatives are:

(1) The importance of securing that suitable hospital treatment is available for every citizen and that recourse to it, at the earliest moment when it becomes desirable, is not delayed by any financial considerations. From this point of view previous contribution is the ideal, better even than free service supported by the tax-payer. People will take what they have already paid for without delay when they need it, and they pay for it more directly as contributors than as tax-payers. But it can be argued that, under the present system, people do not in practice delay taking hospital treatment when they need it; their general practitioner will advise going to hospital as soon as it becomes necessary, and if they are not voluntary contributors they will be asked to pay only according to their means. It is possible that the main practical reasons which now delay recourse to hospital after it has become desirable are not difficulties about paying for the treatment, but either (*a*) deficiency of accommodation or (*b*) unwillingness or inability to give up work or household duties in order to be treated.

(2) Hospital policy, particularly in relation to the place of voluntary hospitals, the terms of service and pay of their staffs, and the desirability or the reverse of allowing arrangements whereby individuals, whether through membership of a voluntary association or by special payment, can get choice of specialists or hospitals or special treatment in them.

(3) Financial policy, and particularly the question of the optimum size of the insurance contribution and of the Security Budget in relation to the ordinary budget.

434. A minor question in the relations of the social insurance scheme and the finance of hospitals is whether persons in receipt of disability benefit on entering an institution should be required to make any payment towards the cost of their board as "hotel expenses." With the small benefits provided by National Health Insurance hitherto, this question could hardly be raised. But if the social insurance scheme is to provide benefits in future designed to cover the food and fuel requirements of the insured person and his dependants, it may appear reasonable that, while such a person is getting his food and fuel in a hospital and not in his home, the money provided for that purpose should be directed to the hospital. The point is not perhaps of great importance to the finance of institutional treatment; a sum of, say, 10s. a week is the most that could fairly be regarded as saved in the home by the temporary absence of the insured person in hospital. But if it appears equitable to make such a charge, it may be expedient to make it, if only in order to avoid making it appear profitable to the patient to stay in the hospital when he could go home.

435. Dental and ophthalmic treatment and appliances are now overwhelmingly the most popular of the additional treatment benefits under National Health Insurance. That is to say, they are being paid for in part by compulsory contributions and for the rest mainly by a charge when treatment is given. There is a general demand that these services should become statutory benefits available to all under health insurance. There appears to be ground for regarding a development of preservative dental treatment as a measure of major importance for improving the health of the nation. This measure involves, first, a change of popular habit from aversion to visiting the dentist till pain compels, into readiness to visit and be inspected periodically; it involves, simultaneously with creation by these means of a demand for a larger dental service, the taking of steps to organize a larger supply of the service. That the insurance title to free dental service should become as universal as that to free medical service is not open to serious doubt. The only substantial distinction which it seems right to make is in the supply of appliances. To ensure careful use, it is reasonable that part of the cost of renewals of dentures should be borne by the person using them. This might possibly be extended to the original supply. The same holds true of optical appliances.

436. Surgical appliances, convalescent homes, and nursing are less widely provided as additional benefits, but are essential to a comprehensive health service. Decision as to making these subsidiary services contributory or non-contributory for the individual depends on the line taken in regard to the major problems of domiciliary and institutional treatment. It is reasonable that insured persons should contribute something for such services, as they have shown themselves able and willing to do in the past; in regard to appliances of all kinds, the terms of supply and renewal must be such as to give an incentive to careful use. But it would be anomalous to require compulsory contributions for special and subsidiary purposes if the main services were non-contributory.

437. This review of some of the problems involved in establishing a comprehensive medical service makes clear that no final detailed proposals, even as to the financial basis of this service, can be submitted in this Report. It suggests the need for a further immediate investigation, in which the finance and the organization of medical services can be considered together, in consultation with the professions concerned and with the public and voluntary organizations which have established hospitals and other institutions. From the standpoint of social security, a health service providing full preventive and curative treatment of every kind to every citizen without exceptions, without remuneration limit, and without an economic barrier at any point to delay recourse to it, is the ideal plan. It is proposed accordingly that, in the contributions suggested as part of the Plan for Social Security, there shall be included a payment in virtue of which every citizen will be able to obtain whatever treatment his case requires, at home or in an institution, medical, dental, or subsidiary, without a treatment charge. It is proposed that the sums derived from these payments shall be transferred to the Department or Departments concerned with the organization of the health service to most part—it can only be part—of the total cost. But these proposals are provisional only, subject to review in the light of the further inquiry suggested, in which organization and finance can be dealt with together. The primary interest of the Ministry of Social Security is not in the details of the national health service or in its financial arrangements. It is in finding a health service which will diminish disease by prevention and cure, and will ensure the careful certification needed to control payment of benefit at the rates proposed in this Report.

438. Assumption B covers not only medical treatment in all its forms but also post-medical rehabilitation. In regard to the latter, as in regard to the former, it would be inappropriate here to discuss details of organization. During the preparation of this Report the practical problems of rehabilitation have been under consideration by the Departments concerned, and it is hoped that practical measures will follow. Rehabilitation is a continuous process by which disabled persons should be transferred from the state of being incapable under full medical care to the state of being producers and earners. This process requires close co-operation between the Health Departments and the Department concerned with employment—that is to say, the Ministry of Labour and National Service. Whether this co-operation can be secured best by the setting up of an executive organ representative of both sides or by allocation of specific duties to each Department is a problem of departmental organization on which it would be inappropriate here to express an opinion. It is sufficient to put forward three general propositions:

(*a*) That rehabilitation must be continued from the medical through the post-medical stage till the maximum of earning capacity is restored, and that a service for this purpose should be available for all disabled persons who can profit by it irrespective of the cause of their disability.

(*b*) That cash allowances to persons receiving rehabilitation service should be the same as training benefit, including removal and lodging allowances where required.

(*c*) That the contributions paid by insured persons should, as in the case of medical treatment, qualify them for rehabilitation service without further payment.

It will be consistent with the proposals made here to include part of the cost of post-medical rehabilitation of men injured in scheduled hazardous industries in the industrial levy of these industries—that is to say, to add a contribution towards the cost of this service to the amount of the levy.

ACTUARY'S MEMORANDUM

Contribution Rates (Para. 34)

The rates of contribution proposed to be paid for all classes include a contribution towards the cost of health services—namely, 10d. for an adult man and 8d. for an adult woman, with reduced sums of 8d. for a young man aged between 18 and 21, and 6d. for young persons aged between 16 and 18 and young women aged between 18 and 21. In all these contributions the employer's share has been taken as 1½d., this being approximately the contribution which employers now pay towards the medical benefit of their employees under the present National Health Insurance scheme.

Health and Rehabilitation Services (Paras. 61–64)

61. The second of the three assumptions stated in the Report to be essential to the institution of the Plan of Social Security is: comprehensive health and rehabilitation services for prevention and cure of disease and restoration of capacity for work, available to all members of the community. The general principles underlying this assumption are given in Part VI of the Report, but it is there indicated that most of the problems of organization in such a service fall outside the scope of the Report. The cost of such a comprehensive scheme clearly cannot be estimated with precision until the proposals have taken more definite shape. It is proposed that the cost should be defrayed out of public funds, subject to a substantial grant-in-aid from the Social Insurance Fund.

62. As indicated in para. 34, the sum available for allocation out of the contributions at the rates proposed is 10d. a week for each adult male contributor in Class 1, 2, or 4, and 8d. for each adult woman in these classes, the corresponding rates for contributors under age 21 being 6d. for a boy under age 18, 8d. for a young man of 18 and under 21, and 6d. for a girl or young woman under age 21. I estimate that the annual income from contributions at the rates stated will amount to about £40,000,000 in 1945. On the basis described in para. 34 relating to the division of the total contributions in Class 1 between employers and workers, it is estimated that about £6,000,000 will be paid by employers, about £26,000,000 by employees in Class 1, and the remainder, about £8,000,000, by contributors in Classes 2 and 4.

63. While, as indicated above, a precise estimate cannot be framed of the gross cost of a comprehensive scheme of the services in question, it is essential at the present stage, in order to measure broadly the liabilities of the Exchequer and other parties arising under the Social Security Plan as a whole, to include an estimate in the Social Security Budget, where the expenditure arising among the various heads is brought together. After consultation with the Ministry of Health and the Department of Health for Scotland, a round figure of £170,000,000 a year has been taken as a suitable measure for this purpose. Assuming a grant-in-aid from insurance contributions of £40,000,000, the net annual cost to public funds would thus be in the neighbourhood of £130,000,000, or rather over three-quarters of the total expenditure.

64. In view of the fundamental changes involved in the substitution of a comprehensive health service, covering the whole population of all ages, for the present arrangements under which, apart from the medical benefit provided for the insured persons themselves, but not their dependants, under the National Health Insurance scheme on the one hand and the various public health services on the other, medical treatment is secured under private arrangements, it is not thought appropriate in the present memorandum to attempt a financial comparison of the two systems. In considering, however, the proposed charge on public funds it is necessary to have regard to the existing charges on the national and local exchequers in regard to analogous services. Before the war the charges on public funds for the services in question may be put at about £45,000,000 to £50,000,000. Making some allowance for development

and for increased prices, it is thought appropriate for comparative purposes to put the cost of the existing services at about £60,000,000 in a post-war year. The net increase in the cost to public funds is thus of the order of £70,000,000.

INSURANCE ACTS COMMITTEE OF THE B.M.A.

A "Beveridge" Special Conference?

A meeting of the Insurance Acts Committee was held on Jan. 21, under the chairmanship of Dr. E. A. Gregg. Dr. T. H. Bates of Newcastle was elected to fill a vacancy on the Committee, and Dr. C. H. Gregory of Rugby and Dr. F. A. Roper of Exeter were welcomed as new members.

One of the principal purposes of the meeting was to discuss certain aspects of the Beveridge Report, in particular the assumption that the medical service envisaged under the scheme will cover the entire population, not 90% (the present insured persons and their dependants) as is assumed in the draft interim report issued by the Medical Planning Commission. It was deemed to be the more urgent to arrive at some expression of opinion on this point in view of the resolution of the recent Annual Panel Conference declaring for 90%. It was decided that a special conference should be called, perhaps jointly—subject to the decision of the Council of the Association—with a Special Representative Meeting.

Capitation Fee: Answer to Deputation

The Committee received a report of a further interview which an appointed deputation had had with the Minister of Health to press the case for a wartime increase in the capitation fee in view of additional work and shift of insurance risk. The Minister had refused the request, stating that increased work was taken into consideration when his previous decision was announced last October. It was contrary to Government policy to recognize additional work as establishing a case for a war bonus. Postponement of payment by way of post-war credit, which had been suggested as an alternative, did not affect the general principle which the Government had felt bound to adopt. On another point which the deputation had strongly pressed—namely, the advantage of the Protection of Practices Scheme as an aid to recruitment of doctors for the Forces—the Minister, while recognizing the importance of the scheme, did not feel that this again afforded ground for an alteration in the Government's general policy.

It was the feeling of the Committee that, faced with this final refusal, the only recourse was to make the public aware of the fact that doctors were giving a large amount of additional service and incurring a perpetually heavier obligation while they were refused any recognition of it in the form of payment, present or prospective. In this connexion an interim report of the Organization Subcommittee was opportunely presented. It contained several recommendations, which were agreed to, for stimulating the formation of group committees, covering a number of Panel Committees in adjacent areas, together with such organization of areas that the views of every insurance practitioner can be ascertained in the shortest possible time, and every practitioner can be informed, with equal expedition, of what his colleagues in general are thinking, and of what is proposed locally and at headquarters. It was also agreed to prepare in leaflet form for distribution to practitioners a statement of the method of election of the Insurance Acts Committee. The Committee is as democratic a piece of machinery as was ever invented, but democracy is largely thwarted if the enfranchised do not know how the machinery works.

More Publicity

A matter further considered was the means which would ensure the regular presentation in Parliament of the views of the profession, and advance information of any intended Parliamentary action in matters in which the profession is concerned. The sponsoring of the candidature of a medical man for the House of Commons was regarded as the most useful method. It was felt also that it was advisable to revive the public relations department, which had been in suspense in wartime, the cost to be shared by the National Insurance Defence Trust and the British Medical Association. A proposal was made at the Annual Conference that an association of insurance practitioners should be formed, the membership and administration to be confined to those engaged in panel practice, but this was turned down alike by the Organization Subcommittee and the Insurance Acts Committee, whose policy is strongly against separatism or what may be called "adjectivism" in the description of members of the profession.

The Deputy Secretary made a report on a discussion with representatives of the Ministry of Health with regard to payment for medical treatment of members of H.M. Forces who have been discharged on medical grounds. He said that it was proposed to pay for such patients 16s. 6d. per annum, exclusive of drugs and mileage—in other words, this amount must be compared with the ordinary capitation fee of 9s. 9d.

BEQUESTS FOR MEDICAL CHARITY

Two generous bequests to the B.M.A. for medical charity were considered at the last meeting of its Executive Committee. The late Dr. B. R. Rygate bequeathed £500 to the Association for this purpose, in addition to making a similar bequest to the Royal Medical Benevolent Fund; while the late Dr. T. Connel Craig left a one-third share of his residuary estate, the total value of which is approximately £20,000, to the Association's Charities Trust Fund. It has been decided to add the names of Dr. Rygate and Dr. Craig to the list of Benefactors of the Association which is displayed at B.M.A. House.

Members who wish to include in their wills legacies for medical charity and who prefer that the money should be paid to the Association and handed over, at its discretion, for administration by one or more of the benevolent funds of the profession, are asked to note that such legacies should be bequeathed to the Charities Trust Fund of the Association, which is not itself a medical charity but merely a collecting and distributing agency. On the other hand, when a member wishes to benefit a particular medical charity he should arrange for that charity to be named correctly in his will. Such vague descriptions as "the benevolent fund of the British Medical Association" are liable to lead to confusion as to the intention of the testator, and much difficulty will be avoided if exact titles are given.

FEES FOR NATIONAL DEPOSIT FRIENDLY SOCIETY MEMBERS

It will be recalled that the Council of the B.M.A. in 1941 recommended general practitioners to increase their private fees, including contract fees, by not less than 20%, and discussions have recently taken place with the National Deposit Friendly Society with a view to securing an increase in the fees paid by this society for the medical treatment of its members. The society agreed that there was justification for an increase in medical charges, but maintained that the scale of benefit allowed to its members was not intended necessarily to conform to the actual charges made by practitioners, although the scale was originally designed to be sufficient to satisfy the normal charges applicable to the working-class community. The society pointed out that the scale of fees now paid was the maximum which its funds would at present allow.

It was suggested to the society that there should be included in its scale of medical fees a statement that the fees paid by the society for the treatment of its members were "grants-in-aid" only, and that they might have to be supplemented by the members themselves. The society agreed to amend its forms by substituting "scale of allowances to members" for "scale of charges." The General Practice Committee of the B.M.A. recommends members of the Association to accept the society's scale of fees as a "grant-in-aid" towards the cost of medical treatment, charging ordinary private fees with a wartime increase of 20%.

INCREASE IN FEES

As a result of representations made by the General Practice Committee of the B.M.A. the following medical fees are announced:

Ministry of Labour Trainees.—The Department has agreed to the following scale for treatment of trainees in respect of whom the Ministry accepts financial responsibility:

(*a*) Doctor's visit (to lodgings), with medicine (first and subsequent visits), 5s.; (*b*) attendance at surgery, with medicine, 3s. 6d.; (*c*) doctor's visit (to lodgings), with medicine, in urgent or dangerous cases between the hours of 8 p.m. and 8 a.m., 10s. 6d.

Women's Land Army.—The Ministry of Agriculture and Fisheries has agreed to pay a fee of 5s. for volunteers who are required to undergo medical examination.

N.A.A.F.I. — This corporation has agreed to pay a fee of 5s. for the medical examination of candidates.

Doctors are especially warned that under Board of Trade Regulations motor cars *if used at any time* for professional purposes, even if now laid up, should be insured under the Business Scheme of the War Damage Act, 1941. They are not covered under the Private Chattels Scheme. This does not apply to doctors serving in the Forces or holding full-time public appointments. The Medical Insurance Agency will be pleased to give all information and effect policies.

Correspondence

Industrial Medical Attendance

SIR,—The letter from Dr. L. H. Eunson (*Supplement*, Jan. 9, p. 7) calls for a brief reply. The attention given by an industrial medical officer to his casualty cases varies greatly according to aptitude, facilities, and time available from many other claims, but the majority regard the care of these cases as the most important part of their job. He sees the patient from the time of injury, has the advantage of a trained nursing staff, and is closely in touch with hospitals most suitable for treatment of industrial injuries. Also his knowledge of the work to which the workman will return often means that he can conserve days and weeks of working time, a factor of the utmost moment at present. The injured workman is quick to seize on the slightest variation of comment as he passes through the hands of panel, industrial, and compensation doctor, and there is much to be said for combining these multiple functions.

The difficulties set forth are imaginary rather than practical, and disappear when an attitude of co-operation and understanding is cultivated on both sides. To take the points raised: (*a*) Of course the patient must have an N.H.I. note. Most M.O.s use the green certificate provided by the B.M.A. This fulfils two functions: it can be stamped as a compensation case by the employing firm admitting liability (a course which saves the patient being pestered by a long questionary from his Society), and, in covering his stamps, commencement of incapacity is certified with exactitude. (*b*) Every workman clearly understands that he is free to consult his panel doctor at any time. The usual practice is to give him a note. The very fact that an industrial M.O. has assumed treatment of an injury is surely presumptive evidence that he is dealing with a compensation claim. (*c*) Few part-time men can supervise follow-through treatment. The suggestion that, where they do so, they would use this zeal to feather their own nests is a little ungenerous and, I am sure, unjustified. I am afraid that I do not grasp the implications of Dr. Eunson's last paragraph on "exemption from duty."—I am, etc.,

Smethwick A. H. DRIVER.

Compensation for Civilian Doctors

SIR,—The case of "Dr. O." quoted in the *Supplement* of Jan. 23 (p. 13) is surely a sad reflection on the inadequacy of the pension offered to the dependants of a hero killed while serving his country in a professional capacity. It is good to learn that, thanks to our Fund, his orphaned children will be suitably provided for, but they owe no debt to anyone. On the contrary, the country as a whole is in their debt, and it is ridiculous for us to talk of social security while these two children mutely accuse the central authorities of a scandalous failure. —I am, etc.,

Gateshead JAMES GRANT.

*** The B.M.A. has made repeated representations to the Government for higher pension rates for dependants of civilian doctors who lose their lives owing to enemy action, but without success.—ED., *B.M.J*

Views on the Panel Conference

SIR,—At a recent meeting of the Somerset Local Medical and Panel Committee my report on the Panel Conference was received. My committee was of the opinion that the views expressed in this report would be of interest to other Local Medical and Panel Committees who may be holding meetings at which the report of their own representative will be received.

The points brought out in my report were as follows. The attendance was very good considering the awful weather, and proves an increasing interest in medical politics. The agenda was again most unsatisfactory—three agendas, with 112 resolutions, amendments, etc. This points to the fact that the agenda committee does not do its work. Many of the amendments and even resolutions could have been cut out if this committee had got in touch with the local panel committees before the conference. If resolutions had to be in one clear month, and all amendments two clear weeks, before the Conference, it would allow many to be withdrawn before making up the final agenda, and would also give local panel committees time to instruct their representatives. It would also allow proper discussion of all resolutions on the Conference agenda. As a profession we are as ununited as ever, and still appear to have no wish to co-operate with other medical bodies against a common foe. Much too much time of the Conference was taken up by the chairman of the I.A.C. or by resolutions put forward by the I.A.C. at the expense of other resolutions put forward by local panel committees. The I.A.C. is beginning to alter its tone in its dealings with the Ministry of Health—a very healthy sign which wants encouraging.

These views are expressed with the idea of increasing the value of the Panel Conference and not in any way to hamper the actions of the I.A.C.—I am, etc.,

Williton C. F. R. KILLICK.

B.M.A.: Branch and Division Meetings to be Held

GLASGOW AND WEST OF SCOTLAND BRANCH.—At Institution of Engineers and Shipbuilders in Scotland, 39, Elmbank Crescent, Glasgow Wed, Feb. 10, 3 30 p m Prof. J. M. Mackintosh. The Social Factor in Disease

B.M.A.: Meetings of Branches and Divisions

VICTORIAN BRANCH

Although the report for the year ending Dec., 1942, of the Victorian Branch of the B M.A. and the Medical Society of Victoria is a much slimmer publication than usual, it reflects a very busy year with increased membership. Scientific meetings were held as follows: Aug., a symposium on "Lymphogranuloma Inguinale," at which the speakers were Dr. H. F. BETTINGER, and Lieut-Col. W C. MCCALLY, Capt. F. MCDONALD, and Lieut. H. JOHNSON, of the U.S. Army; Sept., an address on "Foodstuffs and Feeding" by Col. Sir STANTON HICKS; Oct., the ninth Sir Richard Stawell Oration on "The Principles of Nerve Surgery as Taught by Research in Nerve Regeneration" by Dr. BASIL KILVINGTON; and Nov, the fourth Embley Memorial Lecture on "Anaesthesia in Military Hospitals" by Lieut-Col. W. B. PARSONS of the U.S. Army. The provision of medical men for the Forces engaged the close attention of the Branch Council during the year, and with the establishment of the Emergency Civil Medical Practitioner Service steps were taken to prepare lists of those doctors who could most readily be spared from civil practice. Other matters considered by the Branch Council were the proposals of the Federal Council for a general medical service for Australia (*Medical Journal of Australia*, Nov. 1, 1941) and of the National Health and Medical Research Council for the establishment of a salaried medical service (ibid., Aug. 16 and Dec. 20, 1941). Familiar notes are struck by references in the report to petrol rationing, election to provisional membership of doctors holding licences under the National Security (Alien Doctors) Regulations, and certification for sickness absence from work. The report also includes a list of medical casualties among the members of the Branch; reference to these will be found in "The Services" column of the *Journal*.

H.M. Forces Appointments

ROYAL NAVY

Surg. Cmdrs. J. C Kelly, D S C., and A. C Anderson have been placed on the retired list with the rank of Surg Capt.,

ROYAL NAVAL VOLUNTEER RESERVE

Prob Temp Surg Lieuts. R. R Wethered, A Campbell, A. W. Hetherington, and J. MacDonald to be Temp. Surg. Lieuts.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Capt. N E. Challenger has relinquished his commission on account of ill-health and is granted the honorary rank of Capt.

Lieut A S Craner has relinquished his commission on account of ill-health and retains his rank.

ROYAL AIR FORCE

Temp. Squad. Ldrs H. D-Conway, D. J Sheeham, and J B Wallace to be War Subs Squad Ldrs

ROYAL AIR FORCE VOLUNTEER RESERVE

Temp. Squad Ldrs. H. A. Graham, D. M Anderson, and J. G L Brown to be War Subs Squad. Ldrs

Fl Lieut. P. J W. Mills has relinquished his commission on account of ill-health

Flying Officers J. Jones, D. H. Lambert, and J L Greaves to be War Subs. Fl Lieuts.

To be Flying Officers (Emergency): W. M Bennett, E. J. Grierson, A. J B McFarland, J. C C. Poole, A McC Russell, E. G. Saint, R B Tulk-Hart, A. C Turner.

POSTGRADUATE NEWS

The Fellowship of Medicine announces: (1) Week-end course in rheumatism at Rheumatic Unit, St. Stephen's Hospital (L C C) on Sat. and Sun., Feb 27 and 28; (2) Revision course in anaesthetics at Radcliffe Infirmary, Oxford, March 15 and 26; (3) Clinical surgery, Sat, Feb 27, 2 30 p.m, at London Homoeopathic Hospital, examination of cases and tutorial; demonstration of cases every Wed. afternoon; (4) Fundus oculi demonstration (M R C.P) Wed, March 3, 1 30 p m, at West End Hospital for Nervous Diseases, I.P Dept; (5) M.R C.P course in neurology, Tues and Fri., 3 p.m., March 9 to April 2 at West End Hospital for Nervous Diseases. Detailed syllabuses may be had from the Fellowship of Medicine

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W.—*Brompton Hospital* · Tues and Thurs, 4 30 p m (limited to 6), M R C P course in chest diseases *London Homoeopathic Hospital:* Wed afternoon (limited to 6), Clinical surgery demonstration *National Hospital for Diseases of the Heart:* Tues. and Wed, 10 a m, Out-patient clinics.

BIRTHS, MARRIAGES, & DEATHS

BIRTHS

APPLEYARD—On Jan 20, 1943, at the Buckingham Nursing Home, Leeds, to Jeanne (*née* Garner), wife of Flying Officer O B Appleyard, M A., M B., B.Chir (Cantab.), M R C S, L R C P., a son (Terence Neil).

MASSIE—On Jan 27, 1943, at Mayday Hospital, Croydon, to Fl. Lieut and Mrs. F E. Massie, a daughter (Carol Ann).

TETTMAR—On Jan 26, 1943, at Danbury Park Maternity Home, to Betty, wife of Capt Peter Tettmar, R A M.C (over-seas), a son.

DEATHS

HUNTER.—On Jan 22, 1943, in India, as the result of an accident, Captain Fred Hunter, I M S., of 7, The Steyne, Worthing, Sussex

MACNISH.—On Jan. 21, 1943, at Prestatyn Golf House, North Wales, David MacNish, M A., M D, J P; in his 83rd year. Interred at Prestatyn, Saturday, Jan 23

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY FEBRUARY 13 1943

British Medical Association

PROCEEDINGS OF COUNCIL

ACTION ON THE BEVERIDGE REPORT

A meeting of the Council of the Association was held on Feb. 3, Prof. R. M. F. Picken, Acting Chairman, presiding. There was a full attendance, and the meeting lasted from 10 a.m. to 5 p.m.

PERSONAL

The deaths were reported of five former members of Council and of two sitting members (Dr. J. G. McCutcheon and Dr. A. M. Watts). The Chairman was authorized to forward letters of condolence to the families.

Congratulations were accorded to 24 members of the Association, the recipients of recent honours.

The Boyd Bequest

The Chairman drew attention to the bequest of the late Dr. Robert Boyd, formerly chairman of the Manchester Division, who had left, subject to life interests, the residue of his estate to the Association for the endowment of a B.M.A. House in the district of Manchester for the use of doctors practising in Manchester and its surroundings, the management of the House to be vested in the committee of the local Division.

Mr. R. L. Newell said that Manchester members of the Association greatly appreciated this handsome gift, which answered a long-felt want. He had attended Dr. Boyd during his last illness, but Dr. Boyd gave no intimation of his intentions; but the welfare of the Association was always uppermost in his mind, and his chief concern had been to get well enough to attend the Annual Representative Meeting last September, when he had some contentious resolution to propose.

The Council placed on record its grateful appreciation of the legacy.

Services of Mr. Bishop Harman

At a later stage, in introducing the report of the Executive Committee, the Chairman said that it was felt that this was a suitable occasion to refer to the noteworthy services of Mr. Bishop Harman, who was now no longer a member of Council. His work had already been recognized by the award of the Gold Medal in 1931, but in the years following as well as for many years before that he had been a tower of strength to the Association. In the conduct of debate, where he gave and took thrusts with evident enjoyment, he always showed perfect courtesy, and in his dealings with colleagues and juniors much kindness. In the design of the Gold Medal and in various matters of decoration in the Association's House he had displayed great artistic skill and knowledge. He had been a generous benefactor to the Association, and Mrs. Bishop Harman had established the prize which bore her name.

A resolution placing on record the grateful appreciation of the Council of the unremitting and valuable services rendered to the Association by Mr. Bishop Harman during his continuous membership of the Council from 1915 to 1942, and especially during his fifteen years' (1924-39) tenure of office as Treasurer of the Association, was carried unanimously and with enthusiasm.

THE BEVERIDGE REPORT

The Question of 100% Inclusion

The Chairman said that the report of Sir William Beveridge on social insurance and allied services, including a comprehensive medical service for the whole community, was so important and revolutionary that it was thought desirable for the Association to arrive at some conclusion without delay on the proposal to provide, as a right, medical services for 100% of the population. The Executive Committee held a meeting to which the chairmen of all the standing committees concerned were invited, but on further consideration it seemed desirable that each of the standing committees should meet to consider the matter for itself. The various group committees were also called. The result was that a number of resolutions were now placed before Council, all of the same purport, though differing in phrase. The chief difference was that in some of the resolutions some such wording was used as "would not resist the inclusion of 100%," while in others it was stated that the Association would, in the public interest, "be willing to accept such a scheme"—in each case with certain provisos. The situation was further complicated by the decision arrived at by the Annual Representative Meeting, which by a very small majority decided that provision should be made by the Government for the whole community, although a whole-time salaried Government medical service was rejected. On the other hand, the Annual Panel Conference expressed the opinion that any extension of services should be limited to the present insured, their dependants, and those of like economic status. All this, of course, was prior to the Beveridge Report. It was important to seek as large a measure of agreement in the profession as possible; any considerable minority would be a serious handicap in negotiations with the Government. That was the reason why this long and laborious procedure had been followed.

Each of the chairmen of the standing committees then gave to the Council some account of the feeling of his committee on this subject. Mr. Newell, for the Hospitals Committee, said that if the public considered that what was held out to them was a complete insurance it would mean the end of voluntary subscriptions. He thought that private practice would continue for a considerable period. To debar the State doctor from private practice would create a special section of doctors who did private practice and nothing else, which would be unfortunate. Prof. A. H. Burgess said that the Special Practice Committee considered that if Parliament, after consideration of the Beveridge Report, decided to initiate a scheme for comprehensive health services, available to all members of the community, the Association should be willing to co-operate provided that the terms and conditions of service were determined by agreement with the profession, and that when a beneficiary under the 100% scheme decided to obtain medical services privately he should be free to do so at his own cost, and any practitioner rendering such service should not be precluded, although a member of the scheme, from accepting fees. Dr. Gregg said that the Insurance Acts Committee proposed to submit to the Panel Conference a similar resolution, but the result was by no means a foregone conclusion, and he rather regretted the tendency to bow the head before an alleged public opinion.

The view of the Scottish Committee, put forward by Dr. G. MacFeat, was that even though a 100% service were started on a part-time basis it would develop into a full-time one. In order to maintain a high standard of medical service for the citizen, State-provided service and private practice should be continued concurrently, each acting as a spur to the other. The Government should be informed that it was in the public interest to limit any State-provided service to that section of the community who could not reasonably be expected to afford an adequate medical service out of its own resources. Dr. J. B. Miller, for the Public Health Committee, said that if Parliament decided on a scheme applying to 100% it would be a losing battle to oppose it, but he could not help recalling the situation in 1912-13, when the Association won a great victory, although it never recognized the fact. In all these negotiations there was a substantial minority with more advanced views, and the minority had a large influence in the final settlement. Dr. S. Wand summarized the very long discussion which had taken place in the General Practice Committee, where a recommendation was carried similar to the others and with the same proviso, but using the phrase "would not resist the inclusion of the 100%."

In some general discussion Dr. W. M. Fox said that he thought the Council should welcome the Beveridge Report as a satisfactory extension of present services, but should set up a committee to go into the economics of the subject so far as doctors were concerned in order to be ready for the time when such a service was introduced by the Government.

Dr. A. S. GOUGH said that the acceptance of the 100% was a serious step, but one which must be taken; he thought that the absolute right of the patient to choose a private doctor if he desired, and the right of the practitioner to engage in private practice, should be safeguarded. this must not be relegated to a secondary consideration. Dr. G. W. MILLAR was doubtful whether it was possible to accept the principle of 100% and at the same time demand the continuance of private practice.

Continuance of Private Practice

The PRESIDENT (Sir Beckwith Whitehouse) drew attention to a reference in the report of the Scottish Committee that

> "a differentiation might well be made in the provision of the domiciliary or family doctor service and the institutional and specialist service, and [the Committee] considers that the section of the population above an agreed income limit should be able to pay for their family doctor service, but that the more expensive institutional and specialist service might with advantage be provided for the whole community from the contributions proposed in the Beveridge plan."

He asked whether the Committee had it in mind that the more expensive special services were to be paid on the basis of the elimination of private practice or to be provided by means of grants in aid. He thought the profession would be well advised to accept the 100% without further argument. Dr. MACFEAT replied that the Committee had in mind the class of people who had difficulty in paying for institutional and specialist treatment. Under the Beveridge plan, if the contributions provided £40 million and the State £130 million there might be allocated out of the smaller sum grants to meet the real hardship of the middle class.

Dr. PETER MACDONALD said that the matter of the 100% was for the community to decide, and the chances of the profession influencing the community were small. He was not in favour of grudging acceptance. If Parliament decided in favour of the plan there should be an offer of willing co-operation. He did not agree that the acceptance of the 100% would cut out private practice, which would continue for at least the present generation. Dr. P. INWALD agreed that if Parliament decided on a 100% scheme the profession ought not to be found in opposition, but he thought it would mean the disappearance of private practice. Much private practice had already gone with the inclusion in National Health Insurance of people up to the £420 income level. Mr. MCADAM ECCLES said that personally he would like agreement on 100%, but only provided that the character and terms of service were framed in agreement with the medical profession. He noticed that in his report (para. 428) Sir William Beveridge said:

> "Most of the problems of organization of such a [health] service fall outside the scope of the Report. It is not necessary to express an opinion on such questions, as free choice of doctor, group or individual practice, or the place of voluntary and public hospitals respectively in the national scheme."

Mr. Eccles felt that if the proviso were made a real lever on which the 100% scheme were accepted a great service would be done for the profession.

Dr. N. E. WATERFIELD said that it must not be forgotten that some of their constituents had intimated their unwillingness to accept 100%, and it was very desirable to get unanimity. It would be most unfortunate to have two classes of doctors, one inside and the other outside the State scheme. Dr. WAND pointed out that if the Government decided that payment should be made by means of a stamp which covered a number of items, including the amount for medical services, it would be impossible to dissect that amount away and therefore the 100% would have to be agreed to; but if it provided one stamp for medical services only the position would be entirely different. Dr. F. M. ROSE said that the Council would have to follow the instructions of the general body of Association members, and such instructions would be given in due course. Meanwhile, however, a lead must be given, and he hoped that it would be for the acceptance of the 100%. Dr. P. MACDONALD pointed out that there were sections of the profession which would take strong exception to anything directed to the medical services only; their agreement was dependent upon the approval of the Beveridge Report as a whole.

Resolution and Amendments

The CHAIRMAN then submitted for discussion the following draft resolution which he suggested might form the basis of a recommendation to the Representative Body:

> 1. That if Parliament, after consideration of the Beveridge Report, decides to give general approval to the principles of the Report, taken as a whole, and to initiate a scheme for comprehensive health and rehabilitation services for prevention and cure of disease and restoration of capacity for work, available to all members of the community, the Association would be willing to co-operate in the preparation of such a scheme, provided that the character, terms, and conditions of the medical service are determined by agreement with the medical profession.
>
> 2. That those members of the community who decide not to avail themselves in part or in whole of the benefits of the service open to them should not be precluded from obtaining the medical service they desire from doctors within the scheme, paying for such service privately, with the necessary safeguards to prevent abuse.

Dr. H. W. POOLER moved an amendment to delete the words "to give general approval to the principles of the Report," and to substitute "to put into operation the recommendations of the Report." Dr. F. GRAY asked whether it was the business of the Association to say that it would agree to the medical scheme only if Parliament adopted the Report as a whole. Dr. J. A. BROWN disagreed with the suggestion that these other matters were not their business. He did not believe that the comprehensive health policy would achieve its object unless the other provisions of the Report were carried out.

Dr. Pooler's amendment was carried with two dissentients, and discussion then took place on the phrase "willing to co-operate" as opposed to such phrases as "would not resist." Dr. WAND thought that the phrase "willing to co-operate" would set up in the mind of the Government the idea that they had got the profession where they wanted them. The words "willing to co-operate" were supported by Major SCOTT STEVENSON, Mr. ZACHARY COPE, and Dr. H. G. DAIN, the last-named pointing out that the co-operation was in respect of the preparation of the scheme, not necessarily, should the scheme prove unsatisfactory, co-operation in its working.

An amendment to substitute the phrase "would not oppose" for "would be willing to co-operate" was lost by a very large majority.

Dr. H. B. MORGAN said that it was very important that the public should not get the impression that once again the organized profession was adopting a defensive attitude and preparing for another rearguard action. They should say that they were willing to co-operate and negotiate on any scheme. The important point of the resolution was in the proviso. It seemed to be taken for granted that the Beveridge Report recommended a scheme for a comprehensive medical service; actually this was not a recommendation in the Report, but one of three assumptions.

After some further discussion it was agreed on Dr. MORGAN'S motion that the last phrase of the first section of the resolution should read: "determined by negotiation and agreement with the medical profession." On the motion of Dr. DAIN, seconded by Dr. MACDONALD, the proviso at the end of the resolution was made a double one, the first part concerning agreement with the medical profession as to the conditions of service, and the second part the question of private practice as set out in the second paragraph of the resolution. Dr. Dain said that he regarded this latter as an essential statement of freedom of patient and doctor. The freedom of the patient to go where he liked for his medical attendance, and of the members of the profession to take part in practice outside the scheme, must be protected in this enlarged national medical service.

The recommendation as finally agreed to was in the following form:

> That if Parliament, after consideration of the Beveridge Report, decides to accept the assumptions of the Report, and to put into operation the proposals of the Report, taken as a whole, including a scheme for comprehensive health and rehabilitation services for prevention and cure of disease and restoration of capacity for work, available to all members of the community, the Association would be willing to co-operate in the preparation of such a scheme, provided (*a*) that the character, terms, and conditions of the medical service are determined by negotiation and agreement with the medical profession, and (*b*) that those members of the community who decide not to avail themselves in part or in whole of the benefits of the service open to them should not be precluded from obtaining the medical services they desire from doctors within the scheme, paying for such services privately, with the necessary safeguards to prevent abuse.

Dr. WAND suggested that in the preamble, when the resolution went out to the Divisions, it should be made clear that this did not mean a whole-time State salaried service. Dr. I. D. GRANT said that in Scotland they were very much against a whole-time salaried service, but he would be content if a statement to that effect were in the preamble. It was agreed that this be done.

The Council further decided that a Special Representative Meeting be called to consider this one issue on Wednesday, March 31, and that at the same time there should be summoned a Special Panel Conference, the two bodies sitting together but voting separately, and that Dr. H. G. Dain should be chairman of the combined meeting.

OTHER BUSINESS

Parliament and Publicity

Dr. GREGG, as chairman of the Insurance Acts Committee, brought forward certain proposals for the better presentation of medical views in Parliament. He suggested that action should be taken to promote the candidature for the House of Commons of a suitable practitioner with the necessary qualifications, including an intimate knowledge of insurance practice. Some members of Council thought that it would be preferable to "educate" present medical members of Parliament in Association policy, but it was pointed out that this was already being done, and that some more direct connexion with Parliamentary doings was desirable. The proposal, which was supported by Dr. DAIN, was accepted as a reference to the Executive Committee.

A further recommendation proposed by Dr. GREGG was for the re-establishment as far as practicable under present conditions of office machinery for the collection and collation of medical intelligence, for the appointment on a whole- or part-time basis of a temporary relations officer or adviser on publicity, and for the setting up of a Propaganda Committee authorized to incur certain expenditure to be borne in equal parts by the Association and the National Insurance Defence Trust.

The proposal to embark upon a large scheme of publicity was opposed by Major SCOTT STEVENSON, who said that any necessary correction of misinformation in the Press was already undertaken by the office, and that in the *British Medical Journal* the Association had the best propaganda medium it could possibly desire.

The recommendations were, however, agreed to, and were referred to the Executive and Finance Committees to be implemented.

Insurance Capitation Fee

Dr. GREGG, in an eloquent speech, recapitulated to the Council the strenuous, but fruitless, efforts which the Insurance Acts Committee had made to obtain from the Minister of Health a wartime increase in the insurance capitation fee. The main ground on which wartime increase was reasonably sought was the manifest shift of insurance risk, which had added greatly to the work and obligations of practitioners. At the first interview the Minister, while expressing sympathy, had refused the claim, whereupon the Panel Conference instructed the Committee again to press the matter. The Committee approached the Minister again with certain definite proposals, one of which was that, in view of the stated Government policy to grant no increases, a system of post-war credits might be entertained. It also expressed willingness to have the case submitted to arbitration. The Minister, however, although he handed to the deputation a confidential document which entirely bore out the case they were presenting as to extra work, repeated his refusal. The Committee was deeply disappointed that its just claim should be entirely rejected, and was sending a strong protest to the Minister. He felt that this protest should be supported by other sections of the profession not engaged in insurance practice, and therefore he asked for a resolution from the Council.

Mr. McADAM ECCLES, who said that he had never spoken in Council before in connexion with the Insurance Acts Committee, moved: "That this Council deplores the rejection by the Minister of Health of the reasonable and justifiable application by the Insurance Acts Committee for a wartime increase in the capitation fee." Mr. ZACHARY COPE seconded. The resolution was carried with one dissentient (Dr. Fox).

The Swansea Hospital Dispute

Mr. R. L. NEWELL, chairman of the Hospitals Committee, gave an account of the dispute at the Swansea General and Eye Hospital.

Mr. Newell also reported that following upon a resolution of the Annual Representative Meeting the Hospitals Committee had considered the question of medical committees in hospitals. It was of opinion that in all hospitals there should be medical committees composed of medical staffs above a certain grade, and that where there was a medical superintendent he should be a member or have a right to attend the meetings. The decision as to whether the medical superintendent should be chairman of the committee was felt to be one for each committee concerned, but there should be a right to direct access to the hospital management. This was agreed to.

Miscellaneous

In view of the recent pronouncement of the Ministry of Health concerning diphtheria immunization of children at their homes by the family doctor, the Council decided to recommend to the Representative Body an amendment of its scale of fees, which was drawn up at a time when domiciliary immunization was not contemplated. It is recommended that where injections are given at the home of the child the fee per injection of immunizing material should be not less than 3s. 6d.; when given at the surgery, not less than 2s. 6d.

Prof. BURGESS said that the Special Practice Committee, at the instance of the Physical Medicine Group, had considered the practicability of setting up machinery, somewhat on the lines of the Council of Physical Medicine of the American Medical Association, to prepare and maintain a list of apparatus used in physical medicine which conformed to certain criteria to be defined. The Special Practice Committee was fully in accord with this intention, but was a little doubtful whether such a complicated task should be thrown upon headquarters at the present moment. The Council passed a resolution along these lines, to be implemented at the convenient time.

Reports were presented from the Liaison Committee between the Association and the British Hospitals Association, from the Science and Journal Committees, and from the General Practice and Scottish Committees, the two last being largely concerned with the proposals on the Beveridge Report already debated. Representatives of the Association on outside bodies were also appointed or reappointed.

Medical examination of doctors of military age on the staffs of hospitals is in future to be made at selected E.M.S. hospitals by senior members of the staff. If a doctor is not then considered physically fit the Army Council will arrange for his further examination, so that he can have official information that he has been rejected as unfit. A doctor who is regarded as fit by the civilian examiner will not be further examined unless and until he is nominated for a commission. (Ministry of Health Circular 2722.)

Association Notices

SPECIAL REPRESENTATIVE MEETING

Notice is hereby given that a Special Representative Meeting of the Association will be held in the Great Hall, British Medical Association House, Tavistock Square, London W.C.1, on Wednesday, March 31, 1943, at 1.45 p m approximately, on the requisition of the Council to consider the following motion:

> That it be recommended to the Representative Body that if Parliament, after considering the Beveridge Report, decides to accept the assumptions of the report and to put into operation the proposals of the report, taken as a whole, including a scheme for comprehensive health and rehabilitation services for prevention and cure of disease and restoration of capacity for work, available to all members of the community, the Association would be willing to co-operate in the preparation of such a scheme, provided—
>
> (*a*) That the character, terms, and conditions of the medical service are determined by negotiation and agreement with the medical profession; and
>
> (*b*) That those members of the community who decide not to avail themselves in part or in whole of the benefits of the service open to them should not be precluded from obtaining the medical services they desire from doctors within the scheme, paying for such service privately, with the necessary safeguards to prevent abuse.

By order of the Chairman of the Representative Body.

B.M.A. House,
Tavistock Square,
London, W.C 1.
Feb. 5, 1943.

G C ANDERSON,
Secretary.

SPECIAL CONFERENCE OF REPRESENTATIVES OF LOCAL MEDICAL AND PANEL COMMITTEES

Notice is hereby given that a Special Conference of Representatives of Local Medical and Panel Committees will be held at British Medical Association House, Tavistock Square, London, W.C.1, on Wednesday, March 31, 1943, at 3.15 p.m., to consider the following motions:

> That if Parliament, after consideration of the Beveridge Report, decides to initiate a scheme for comprehensive health and rehabilitation services for prevention and cure of disease and restoration of capacity for work, available to all members of the community, the profession, in the public interest, should not oppose such a scheme, provided that the character, terms, and conditions of the medical service are determined in agreement with the medical profession.
>
> That those members of the community who decide not to avail themselves of the benefits of the service open to them should not be precluded from obtaining the medical services they need from doctors within the scheme on a fee-paying basis, with the necessary safeguards to prevent abuse.

B.M.A. House,
Tavistock Square,
London, W.C.1.
Feb 5, 1943.

G. C ANDERSON,
Secretary

COMBINED CONFERENCE

There will be a conference of the Special Representative Meeting and the Conference of Representatives of Local Medical and Panel Committees on Wednesday, March 31, at 9.30 a.m. followed, at the times stated in the notices above, by separate meetings of the two bodies, with separate voting.

B.M.A. House,
Tavistock Square,
London, W.C.1.
Feb. 5, 1943.

G. C. ANDERSON,
Secretary.

PUBLIC HEALTH POLICY

The principal business before the Public Health Committee of the B.M.A. at its meeting on January 27 was to consider certain aspects of the Beveridge report. The resolutions adopted, like similar resolutions carried by other committees of the Association, will all be brought before the Council in due course, and on the basis of them recommendations may be shaped to be brought before the Representative Meeting. The particular point put before this Committee as before others was the assumption in the report that the medical service scheme will cover 100% of the population, but the ascertainment of the views of the committees on this point was only preparatory to Council decisions.

The recent circular on diphtheria immunization issued to local authorities by the Ministry of Health was considered, especially the statement that where it was not found possible to secure the attendance of a child at some convenient centre the child should be treated at home, and that to this end the services of medical practitioners in their capacity as family doctors should be utilized. The scale of fees agreed by the Association when the services of general practitioners were utilized in diphtheria immunization provided a sum per injection of not less than 2s. 6d., but domiciliary attendance was not then considered. The Committee agreed that when immunization was carried out at home the fee should be 3s. 6d., the material as in the other case being supplied without charge to the practitioner, both this fee and the fee for injection at the surgery being subject to the 20% wartime increase. It was the general view that the number of cases in which the child was not able to attend at the surgery would be very small or even negligible. A proposal by the Holland County Council that such of its health visitors as were trained nurses should be allowed to give injections in the homes of children of over 1½ years of age was brought to the attention of the Committee, whose view was that the proposal could not be approved.

The question of the use of anaesthetics by midwives, which was the subject of a lively debate at the Aberdeen Meeting in 1939, again came forward at the instance of the General Practice Committee, which had had referred to it an earlier suggestion from the Public Health Committee that the policy might be reconsidered in the light of experience gained by the use of approved apparatus for the administration of nitrous oxide and air as an anaesthetic in labour. The General Practice Committee was hesitant about reopening the subject, but it was desired to know what was the nature of the experience mentioned. Some members of the Public Health Committee stated that the apparatus in question had been used in hospital with great satisfaction and without any unfortunate results, but there appeared to be no body of information as to its home use, and in any case the necessary transport was a difficulty. In hospital, of course, any midwife using it would be more or less under supervision. One member stated that the prospect of having this apparatus at hand in emergency was a factor which determined many women to enter the hospital for their confinement rather than to have it at home. It was decided to ask each member of the Committee to send in any available information as to experiences of the method.

Among other matters with which the Committee dealt was one in which an assistant medical officer of health alleged unkind treatment at the hands of her authority. She had sent in her resignation owing to domestic reasons, but subsequently, on a change of circumstances, had withdrawn it. Neither her resignation nor her withdrawal had been acknowledged, but the authority had proceeded to make another appointment. It was decided to request the observations of the medical officer of health of the authority, and also to consult the Association's solicitor on the legal position.

MEDICAL WAR RELIEF FUND

FORTY-SECOND LIST

Amount previously acknowledged, £47,936 13s. and £100 3½% Conversion Stock and £40 3% Defence Bonds

Individual Subscriptions

£50.—Mr. G. H. Steele, Guildford (2nd donation)

£10 10s.—Mr. A. L. Moreton, Luton.

£5 5s.—Dr. M. L. V. Andrews, Truro; Dr. W. F. T. Haultain, Edinburgh (2nd donation); Dr. J. F McConchie, Wolsingham (2nd donation); Mr. E. H. and Dr. Helen R. Rainey, Harleston, Dr. G. Mary Rolfe, Exeter (2nd donation); Mr. D. N. Rocyn-Jones, Cardiff (3rd donation).

£42 6s. 6d.—Newcastle-upon-Tyne (6th donation).

£25 19s. 11d.—East Lothian (7th donation)

Total—£48,300 19s. 7d, and £100 3½% Conversion Stock and £40 3% Defence Bonds

Cheques, payable to the Medical War Relief Fund, should be sent to Dr. G. C Anderson, Honorary Treasurer of the Fund, British Medical Association House, Tavistock Square, London, W.C 1.

MEDICAL PRACTITIONERS (FEES) REGULATIONS, 1940

The fees payable to doctors called in by midwives under the Midwives Acts are governed by a series of conditions, details of which are given in the Medical Practitioners (Fees) Regulations, 1940. The fees set out in paragraphs (i), (iii), and (iv) of the scale for attendance during labour, for suturing the perineum, etc., and for attendance at an abortion or miscarriage are not payable unless at the conclusion of his attendance the doctor furnishes to the medical officer of health of the local supervising authority a report in the form set out in the second schedule of the regulations. In this connexion the practice of using one form only for the doctor's account and report (where a report is necessary) is one that might appropriately be extended, as it reduces to a minimum the practitioner's clerical work. Much of the information in the special report required by the regulations is in many cases already included in the account form normally used by local authorities. The addition of a few extra items to the account form would dispense with a separate form for the special report.

POSTGRADUATE NEWS

The Fellowship of Medicine announces: (1) Week-end course in rheumatism at Rheumatic Unit, St. Stephen's Hospital (L.C C), on Sat. and Sun., Feb 27 and 28; (2) Revision course in anaesthetics at Radcliffe Infirmary, Oxford, March 15-26; (3) Clinical surgery, Sat, Feb 27, 2.30 p.m., at London Homoeopathic Hospital, examination of cases and tutorial; (4) Fundus oculi demonstration (M.R C P), Wed., March 3, 1 30 p.m., at West End Hospital for Nervous Diseases, In-patient Department; (5) M.R C.P. course in Neurology, Tues. and Fri, 3 p.m., March 9 to April 2, at West End Hospital for Nervous Diseases.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W.1—*Brompton Hospital*, Tues. and Thurs, 4 30 p.m., M.R C P. course in chest diseases (limited to 6). *London Homoeopathic Hospital*: Wed. afternoon, Clinical Surgery Demonstration (limited to 6). *National Hospital for Diseases of the Heart*: Tues and Wed, 10 a m., Out-patient clinics.

EDINBURGH POSTGRADUATE LECTURES.—At Edinburgh Royal Infirmary. *Thurs.*, 4 30 p m. Dr H Stalker: Social Psychiatry.

DIARY OF SOCIETIES & LECTURES

ROYAL SOCIETY OF MEDICINE.—*Wed.*, 2.30 p.m Section of Comparative Medicine. *Thurs.*, 2 p m Section of Dermatology; 4.30 p.m. Section of Neurology *Fri*, 3 30 p.m Joint meeting of Section of Obstetrics and Gynaecology and Medico-Legal Society *Sat.* (Feb 20), 11 a m. Section of Physical Medicine, at Royal Westminster Ophthalmic Hospital.

BIOCHEMICAL SOCIETY.—At British Postgraduate Medical School, Ducane Road, W, *Sat* (Feb 20), 12 noon. Communications and Demonstrations.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.—*Mon.*, 4 30 p.m Discussion: Advances in the Knowledge of Bright's Disease. To be introduced by Dr. Horace Evans.

ROYAL NATIONAL THROAT, NOSE AND EAR HOSPITAL, Gray's Inn Road, W.C.—*Fri.*, 4 p m., Mr J. S. Hogg. Cardiospasm

B.M.A.: Branch and Division Meetings to be Held

PERTH BRANCH.—At Queen's Barracks, Perth, Thursday, Feb. 18, 8 30 p.m, Capt. R. Good, R A.M.C.: Lecture and practical demonstration of the Army Group Selection Tests

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s 6d This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue

BIRTHS

AYLWARD.—On Feb. 2, 1943, at Summercourt Nursing Home, Southborough, to Effie (*née* Munro), wife of Dr. R D. Aylward—a son.

HILSON.—On Jan 29, 1943, at the Westminster Hospital, to Lena (*née* Walker, L.R.C P &S.Ed.), wife of Don Hilson, B.A., M.R.C P, L.R C.S., a son.

LINNELL.—On Feb 2, 1943, at 20, Howard Place, Carlisle, to Mary (*née* Graham), wife of Capt Louis Linnell, R A.M.C—a son (John).

MACARTNEY.—On Jan. 22, 1943, at Crumpsall Hospital, Manchester, to Joyce (*née* Worthington), wife of Major Donald W. Macartney, R A.M C—a daughter

ROSS.—On Jan. 5, 1943, to Betty (*née* Booth), wife of Dr Kenneth M Ross of Farnham, Surrey (Major R A.M C., India), a sister for Angus (Susan Jane).

DEATHS

DONALD.—On Jan. 5, 1943 (the result of an accident), Robert Donald, M C., M D., D.P.H, beloved husband of Helen Cassels, Donachai, Bishopton

THOMSON.—On Jan. 29, in Edinburgh, as the result of an accident, Sir StClair Thomson, M D, F R C P., F.R C.S., late of 64, Wimpole Street, London, son of the late John Gibson Thomson of Ardrishaig, and grandson of the late John Sinclair of Loch Aline, Argyll, aged 84 Cremation (private) took place in Edinburgh. Memorial Services were held at Golders Green Crematorium on Wednesday, Feb 3, and at King's College Hospital, Denmark Hill, on Thursday, Feb 4.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY FEBRUARY 20 1943

Correspondence

Vaccination—An Experience

SIR,—Speculative practice in medicine is unethical, and rightly so, yet the remuneration of the public vaccinator is contingent on the successful result of the operation, and is not made for the performance of vaccination.

During the period in which the Glasgow outbreak of small-pox occurred last year, I had the unusual experience of finding that of 12 consecutive entries in my vaccinator's register 7 related to unsuccessful vaccination, whereas of the previous 100 performed by me only 6 were unsuccessful. My comment that the potency of the lymph appeared low (dilution owing to increased demand from Glasgow) was denied by a Ministry of Health official, who gave his opinion that my ignorance of the principles of vaccination was responsible.

This page in my register brought to my notice the speculative character of public vaccination, and I observed that in one case alone I had paid six visits, travelling 42 miles, vaccinated thrice, completed seven forms and three double entries in a register, all for the sum of one shilling, obtainable after sending to the county council an analysed form of account for the quarter, to be followed later by an analysis of public vaccination for the year. After correspondence with the county council, in which I drew attention to the unsatisfactory nature of the contract, and suggested that payment for work done should be the basis of a future contract, I resigned. My neighbours refused to undertake the district, and now I learn that a practitioner residing over 12 miles away has been appointed, who may yet discover that travelling 192 miles in an endeavour to produce "successful" vaccination in an insusceptible infant for the sum of one shilling is uneconomic and unethical.—I am, etc.,

Tollerton, York. A. K. THOMAS.

The Beveridge Report

SIR,—We have now had a fairly long discussion in your columns and elsewhere on the effect of the Beveridge report on the future of the medical profession. Is it not time that an effort was made to crystallize our attitude to the main proposals in that report? Organizations other than the B.M.A. are sending out questionaries on matters of compensation for practices in the event of their being taken over by the Government, and it cannot be denied that there is a general feeling that we have no united policy to present to the Government when the discussions begin to take place in Parliament. Insurance societies and friendly societies and other interested bodies are making their objections or agreement vocal in the public press and elsewhere, while we are whirling round in a maelstrom of discussion that is leading us nowhere.

Is it not possible for the B.M.A. to prepare a questionary addressed to all practitioners in the country to secure a unified consensus of opinion on the main points affecting us in the new proposals? Such an opinion, backed by the majority of practitioners in the country, would be of immense strength in presenting our case. None of us wants universal panel practice. None of us really likes panel practice from a purely medical point of view, but we appreciate the financial advantages. All of us want an assurance of adequate compensation in the event of our practices being taken over. Many of us do not see how the scheme can possibly work in rural areas. All these points could be dealt with in a questionary. What we need is a defined policy supported by the expressed opinion of the profession as a whole, and not merely by representatives at a B.M.A. conference. Such a statement of policy can be achieved by the method I have suggested.—I am, etc.,

Histon, Cambs A. E. MOORE.

SIR,—Dr. A. Wiseman's letter (*Supplement*, Jan. 30, p. 15) needs a reply from those of us who believe that a State Medical Service would indeed mean a form of slavery for medical men. If Dr. Wiseman had attended the recent inaugural meeting of the Individualists Society, and had seen the crowded hall—the audience being composed of members of all political parties—he might not have thought the Beveridge report commanded such universal approval as given out by the Press. He would, too, have been made aware that the lay public are keenly aware of the disadvantages of a State Medical Service had he heard the speech of Sir Frederick Hamilton, which emphasized the dangers of such a service. Unfortunately, for one reason or another, the Press either omitted all reference to the meeting or gave it but small space. I recommend Dr. Wiseman to obtain a copy of Sir Ernest Benn's speech and to read it.—I am, etc.,

RUSSELL STEELE.

Beveridge Report and Medical Planning

SIR,—A meeting of the medical profession in Bristol was held on Jan. 21, at which there was an attendance of 59. The following resolutions were passed: (1) That this meeting, representative of the medical profession in Bristol, urges the Medical Planning Commission to study without delay the implications of the Beveridge report, with special reference to conditions of service and remuneration. Carried unanimously. (2) That any future medical service should be based on the family, both for the promotion of positive health and for the treatment of disease, rather than on clinic systems of selected groups of individuals—e.g., school children, factory workers, etc. Carried with one dissentient.—I am, etc.,

H. M. GOLDING,
Hon. Sec., Bristol Division, B.M.A.

NEW HOSPITAL PROVIDENT SCHEME FOR LONDONERS

Members of the middle classes often find it difficult to meet the cost during illness of the private ward in a hospital or a nursing home. There has been no provident scheme to enable them to insure against the misfortune of illness in the same way as people with smaller incomes could insure by belonging to a hospital contributory scheme. So far as London is concerned, however, this position is to be altered. A provident fund to cover hospital and/or nursing home charges for people of moderate means has just been launched by the London Association for Hospital Services, Ltd., a non-profit-making concern which is sponsored by the King Edward's Hospital Fund for London. There is no lower or upper income limit; anyone may become a member provided he is not over 60 and either lives or works in the London Metropolitan Area. The annual rates of subscription are, for a single subscriber, £2 12s.; subscriber with one dependant, £4 4s.; with two dependants, £4 16s.; with three dependants, £5 2s.; and with four or more dependants, £5 5s. For these payments a subscriber of six months' standing is entitled to benefits up to a total of £105 annually towards hospital or nursing home charges, fees of doctors, surgeons, and anaesthetists while in hospital, consultations during treatment, and the costs of radiodiagnostic services, pathological and bacteriological investigations, and radiotherapy. No contribution is made towards preliminary consultation fees or for mental cases, confinements, war injuries, cases of pulmonary tuberculosis, notifiable diseases, incurable or senile cases, medical cases treated by the patient's own doctor at his surgery or at home, or dental and ophthalmic cases. While the total sum paid in benefits in any one year may (as stated) be £105, there is a fixed scale of allowances for the individual services likely to be required—i.e., the grant towards the cost of a major surgical operation is limited to £26 5s. in any one year, for consultations during treatment £6 6s., and for a course of radiotherapy £25 5s. in any one year. The scheme has been drawn up with the general approval of the voluntary hospitals and in consultation with the B.M.A. to ensure that it is acceptable to the medical profession. The chairman of the council of management is Sir Bernard Docker, and among the members are Sir Hugh Lett, Dr. G. C. Anderson, and Dr. W. Russell Brain. The offices of the association, of which Mr. T. W. Place is the secretary, are at 10, Old Jewry, London, E.C.2.

The Minister of Health has informed the Pudsey Town Council that, after considering the evidence at the public inquiry into the council's application for permission to terminate the appointment of their medical officer of health, Dr. E. O. Bowie, he has decided that he would not be justified in consenting to Dr. Bowie's dismissal.

THE NATIONAL EYE SERVICE

A meeting of the Ophthalmic Group Committee of the B.M.A. was held on Jan. 15 under the chairmanship of Dr. O. G. Morgan. The first act of the Committee was to place on record its profound appreciation of the services of Mr. Bishop Harman during his term of office as chairman of the former Ophthalmic Committee from 1929 to 1938 and of the Group Committee from 1938 to 1942. This was proposed by Dr. J. L Wilson, seconded by Mr. Harrison Butler, supported by Mr. H. R. Bickerton, and carried unanimously.

The chief business of the meeting, like that of the other committees, was to consider certain aspects of the Beveridge report, especially the question whether the comprehensive service envisaged should be available to the whole of the community. On this point a long exchange of views took place, and the feeling of the Committee was presented to the Council at its last meeting.

The question of the fee for ophthalmic medical examinations under the National Eye Service was again considered. Here again the Beveridge report raised its head. While those working the service do not want to take more than half a guinea from people earning less than £5 per week, they do not see why they should examine people with higher incomes for less than a guinea. But as the Beveridge report has not yet been discussed in Parliament it seemed an inappropriate time to force the issue. It was suggested that although the Beveridge scheme declared for 100% of the community coming into the provided service the conditions would be different. If a contributor had to visit a clinic he would be less likely to seek these services at a cheaper rate. At the present time not all towns have clinics, and the surgeons in these places have to see the patients in their consulting rooms.

The Committee decided to reaffirm the policy of differential rates (that is, for persons whose incomes are under £250, a rate of 10s. 6d., and for those whose incomes are over £250 and under £420, one guinea), and to circularize constituents advising them that although this policy had been reaffirmed it was not proposed at this stage, pending the outcome of the deliberations on the Beveridge report, to enforce it.

The remainder of the business before the Committee concerned a question of disciplinary control affecting a member of the service, and an application for inclusion in the Association's Ophthalmic List.

ASSOCIATION NOTICES

Election of Member of Council by Kent and Sussex Branches

Notice is hereby given that owing to the death of Dr. A. M. Watts a vacancy exists on the Council for the Kent and Sussex Branches. Nomination of candidates for the remainder of the period 1942-3 must be forwarded in writing so as to reach me by March 15, 1943. Candidates must be nominated by either (*a*) a Division or (*b*) not fewer than three members of a Branch in the group, and must be members of a Branch included in the Group, and members of the Association for at least the period of three years immediately preceding the election.

If more than one candidate is nominated voting papers will be issued on March 29 to each member of the Group.

G. C. ANDERSON,
Secretary.

Diary of Central Meetings

Special Conference of Representatives of Local Medical and Panel Committees, 3.15 p.m.

Branch and Division Meetings to be Held

EASTBOURNE DIVISION.—Joint meeting with Eastbourne Medical Society at Princess Alice Hospital, Eastbourne, Tues, Feb. 23, 8 30 p m. Wing Cmdr R W. Durand: Medical Problems of Operational Flying.

APPOINTMENTS

DAVIS, HAROLD, M.B., B.Chir., M R C.P, Temporary Physician to Out-patients, Hampstead General and North-West London Hospital.

GOODWILL, SIBYL D., M R C S., L R C P, D P.H, Temporary Assistant Medical Officer, Metropolitan Borough of Islington.

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s 6d This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue

BIRTH

HALLINAN—On Jan 30, 1943, at the War Memorial Hospital, Crickhowell, Breconshire, to Margery (*née* Pullin), wife of Flight Lieutenant F. J Hallinan, M.B., B.Ch.(N.U.I.), a son (Phillip Edward).

MARRIAGE

ORR—STARK—At Knightswood Baptist Church, Glasgow, on Feb 9, 1943, by the Rev. J. Allan Brown, M A, B D, assisted by the Rev W F Gibbons, B D., of Alloa, Flying Officer John Orr, M B, Ch.B, R A.F V R., only son of the late John and of Mrs Orr, 11, Church Street, Alloa, to Helen Guthrie Chalmers, S R G &F N, elder daughter of Mr and Mrs. Robert A. Stark, 5, Lincoln Avenue, Glasgow, W.3.

DEATH

STIRLING—On Feb 7, 1943, at the Private Patients Home, Manchester, Dr. James M. Stirling, age 47 years, beloved husband of Greta Stirling, "Heversham," 357, Stockport Road, Levenshulme, Manchester.

The Minister of Health announces (Circular 2763) that the restriction placed last June on the promotion of holders of A and B2 posts is suspended, but any proposed transfer of a Class A officer to a B2 post or of a B2 officer to a B1 post must be notified to the Central Medical War Committee, where practicable, at least a month before it is due to take place. The restriction on the transfer from one hospital to another of holders of B1 posts (*Supplement*, Aug. 22, 1942, p. 20) is to continue until April 30 next.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY FEBRUARY 27 1943

Correspondence

The Panel Conference

SIR,—I am asked to forward the following resolution, which was passed at a meeting of the Bristol Panel and Local Medical Committee on Feb. 16, for publication in the *Supplement*:

"This committee, having heard its Representative's report, is dissatisfied with the proceedings at the Conference of Representatives of Local Medical and Panel Committees on Nov. 12, 1942, particularly relating to: (1) the arrangement of the agenda; (2) the amount of time occupied by the chairman of the Insurance Acts Committee and by resolutions put forward by the Insurance Acts Committee; (3) that a motion was accepted for the agenda which was saved from being ruled out of order only by its withdrawal."

—I am, etc.,

Bristol. J. A. BIRRELL, Hon. Secretary.

Insurance Capitation Fee

SIR,—In the report of the proceedings of the Council (*Supplement*, Feb. 13, p. 25) I note that you have named me as the one dissentient against the resolution deploring the Ministry of Health's rejection of a wartime increase in the capitation fee. I consider that either you should have reported the statement I made on the motion or you should have omitted my name.

I stated that while the reasons for demanding a wartime increase were valid, my own feeling was that our position should be considered against the background of an almost completely mobilized nation of forty-five millions, the vast majority of whom were working extremely long hours, and whose economic standards were much lower than those of the medical profession.

Under these circumstances I thought: (*a*) that we should be most unlikely to obtain a bonus, even after further pressure by the Insurance Acts Committee, as stated by Dr. Gregg; and, therefore, (*b*) from the strategical standpoint it might be wiser to keep our eye firmly fixed on our real object, which is an overall increase in the capitation fee, irrespective of war conditions, and that our sacrifice of a war bonus claim would be made use of at the appropriate time. This, I hope, will make it quite clear that my opposition was not on a question of principle but purely on a question of strategy.—I am, etc.,

WILLIAM W. FOX.

SIR,—I see that the Minister has finally refused our just claim for an increased capitation fee on the grounds that "it was contrary to Government policy to recognize additional work as establishing a case for a war bonus," and has completely ignored the prime cause of our dissatisfaction—namely, the altered insurance risk.

We have at our disposal a ready means of obtaining for ourselves the increase so curtly refused by the authorities. All that is required is three months' notice to the Minister that the terms of service will be altered—by us, this time, for a change —and that (*re* para. 6 of the Terms of Service) we propose to make a charge of 1s. for every insurance certificate issued. On the assumption that a practitioner with a 1,500 list will issue 10 certificates —first, intermediate, or final—each weekday, this charge will amount to about 3,000s. a year, and will be equivalent to an increased capitation fee of 2s.: not enough, but probably as much as one could have hoped for at the present time. This notice, and a large placard for the waiting-room to be exhibited well in advance of the proposed change, are all that are necessary.

We must do something about this refusal forthwith. Every month's delay lends weight to the assumption that we are only mildly discontented with our present lot. I can well foresee the time when a future Minister of Health will use the return of our A1 patients from the Forces as a reason for lowering the capitation fee again. What about it, I.A.C.? —I am, etc.,

Preston. L. F. UNSWORTH.

Freedom from Want for Doctors

SIR,—Has not the moment arrived when the most pressing need is for the profession to give serious attention to "social security" and "freedom from want" for doctors? Both in and out of the Press we are in danger of being smothered with plans, which, it is alleged, will improve the standard of medical care of the public, but always the question of the material well-being of the doctor is dismissed with vague phrases such as "adequate remuneration will be paid."

Now that meetings are to be held to consider the Beveridge report, would it not be well for all Divisions of the B.M.A. to be asked to express a definite opinion on this matter? The view of Government circles on the matter is shown by Service, industrial, and E.M.S. salaries—£600 for the G.P. and £900 for the consultant, with a few administrative posts at a slightly higher figure.—I am, etc.,

Whetstone, N.20. A. C. ELKIN.

Industrial Medical Attendance

SIR,—I gather that Dr. A. H. Driver's letter (*Supplement*, Feb. 6, p. 22) is, in effect, a statement that there is no need for an industrial M.O. to be limited by such ethical duty advised by the B.M.A. as referring a case of industrial accident to the practitioner concerned, despite the factors created if he does not do so. At least, I cannot find any clarity in his letter on this point, as he states that most M.O.s use the green certificate provided by the B.M.A., signifying the patient is not referred to the G.P., and then contradicts himself by stating that the usual practice is to give the patient a note to take to his panel doctor. The latter is, of course, the correct procedure, and by offering the facilities of the industrial clinic on the same note the industrial M.O. can still continue his interest in the treatment of the case if he so wishes.

Your correspondent would thereby obtain the co-operation he advocates: he nullifies co-operation by omitting reference to the practitioner. He suggests the advantages he has over the practitioner—i.e., the trained nursing staff, the closeness of touch with the most suitable hospitals, and his greater ability to conserve working-time—and I therefore infer that he doesn't want co-operation from the practitioner but subservience. Finally, I wish to correct his inference that I suggested the industrial M.O. would utilize follow-through treatment to feather his own nest. I stated that by not conforming to ethical rules he would automatically involve himself in such a factor.—I am, etc.,

Tipton, Staffs. L. H. EUNSON.

*** This correspondence is now closed. —ED., *B.M.J.*

N.H.I. Disciplinary Machinery

SIR,—Dr. A. Harbour's unique interpretation (*Supplement*, Jan. 30, p. 17) of the statement in my article with regard to the N.H.I. disciplinary machinery hardly calls for a serious rejoinder, and your space is valuable. But when he goes on to impugn the conduct of the committee over whose deliberations I have had the honour to preside for fifteen years, may I ask him to accept my assurance that he is gravely mistaken.—I am, etc.,

Croydon. R. W. HARRIS.

Naval Medical Officers' Pay

SIR,—In the recent increase of pay granted to junior officers in the Navy members of the medical service were excluded, in spite of the fact that the cost of living has risen equally for medical officers. Since the proportion of pay to that of the other branches of the Service was considered equitable before this increase, it is difficult to see why we of the medical branch were excluded. The position and tendency require careful watching, and I hope this is being done.—I am, etc.,

NAVAL MEDICAL OFFICER.

Medical officers of health are asked to inform the Ministry (Circular 2751) of any men born in the year 1925 who have a history of tuberculosis. The information should be given, as in the case of other age groups, on Form T 147.

H.M. Forces Appointments

ROYAL NAVAL VOLUNTEER RESERVE

Prob. Temp. Surg. Lieut. J. MacP. Jolly to be Temp. Surg. Lieut.

Poole, M B , Ch.B., Medical Officer, Fiji

ABSENTEEISM AND CERTIFICATION

At a recent meeting called by the Nottingham Branch to discuss problems of certification, Mr. Raymond Evershed, K.C., Regional Controller for Fuel and Power, was invited to speak on certification among miners, since coal-mining is one of the main industries of the area It was first pointed out that it was not the case that a man who had been away from work was not permitted by the management to start again unless and until a medical certificate was produced. Mr. Evershed then said that in the coal-mining industry there was the ordinary "civil" contract between the colliery undertaking and its workmen, but there was nothing in that contract requiring a doctor's certificate before a man resumed work after absence In the ordinary contract with a collier or surface worker the colliery did not guarantee to provide work or to pay the workman, however willing and ready he might be to work, if there was nothing for him to do. Thus, if, by reason of a breakdown or because the company was at the time unable to sell its coal economically, the company decided that a pit or seam must "stand," the workmen affected became unemployed. Under the Essential Work (Coal-mining Industry) Orders, 1941 and 1942, it was a criminal offence for a workman in the industry to absent himself from work "without reasonable excuse"—i.e., if, according to the contract of service, he was bound to offer himself for work six days a week (which was usual), then it was unlawful for him not so to present himself on each of the six days unless he had a "reasonable excuse."

There was no definition of the phrase "reasonable excuse," but it was obvious that incapacity from accident or illness was such an excuse, and also that the best evidence of such incapacity was that of a doctor who had examined the man at the material time. The collier was guaranteed a wage whenever he was ready and willing to work, according to his contract, notwithstanding that, by reason of breakdowns, etc., he might not be called on or permitted to do any work, and a levy was imposed on the industry to provide the necessary funds. This guaranteed wage was a weekly, not a daily, assessment, and the man was not entitled to an essential work payment in respect of a day on which he had been absent, however reasonable the excuse might have been. Thus, if a man was absent for any reason at all on, say, a Monday or a Tuesday, and on the remaining days of the week the pit was working normally, no question of an "essential work payment" arose. If, however, having been away on Monday or Tuesday, he found on Wednesday that his pit was "standing" on account of a breakdown, he would be disqualified from claiming an "essential work payment" unless he could show that his absence on Monday or Tuesday was for a "reasonable excuse"; but having so shown, he still did not get any payment for Monday or Tuesday, his guaranteed weekly wage being reduced by the amount due for those two days.

It followed, Mr. Evershed continued, that from the point of view of wages it was hardly ever necessary to give a certificate, and the only cases in which the production of a certificate would be a real and proper protection to a man after a day or two's illness would be when an "essential work payment" was affected. In most of these cases a certificate could as easily be given four or five days after the cessation of the illness as one or two days thereafter. No special form of certificate was required. In all cases the main consideration was that the practitioner must have examined the man on the date of the illness. He could then certify his opinion of the man's condition and of his fitness or unfitness for work

Mr. Evershed concluded by saying that he had sent a circular to all concerned to make certain there was no misapprehension on the part of managements about the legal position, and that men were not denied the right to resume work in the absence of a medical certificate.

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s. 6d This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

DEATH

CRAIG —At 6, Hermitage Terrace, Edinburgh, on Feb 16, 1943, Christina Jane Gibson, widow of the late Archibald Craig, M D., Pathhead Ford, Midlothian, in her 93rd year.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MARCH 6 1943

FUTURE OF MEDICINE IN GREAT BRITAIN

PROPOSALS OF "MEDICAL PLANNING RESEARCH"

"Medical Planning Research" is a body of 400 members, for the most part doctors, many of them serving in the Forces, who have been qualified for less than 21 years, which has been engaged in preparing a plan for the future of medicine in Great Britain. Its interim report was published as a supplement to the *Lancet* of Nov. 21, 1942. The report is an amalgam, by a small editorial board, of 200 individual drafts, many of them expressing divergent opinions, with the result that, as is freely admitted, some of the contributors will be among the most vigorous opponents of the report as a whole.

The difficulty of comparing this interim report with that of the Medical Planning Commission, which anticipated it by a few months, is the totally different approach to the problem. The Commission began its interim report with a criticism of present medical services and went on to discuss improvements; the interim report of Medical Planning Research proceeds from the principle that medical organization is very largely determined by the pattern of the society in which it exists. Fully half the report is concerned with social security proposals, some of which might be leaves out of the Beveridge report if that had appeared before this was constructed. Questions of productive capacity, the causes of poverty, the distribution of purchasing power, housing in its effect on health, are discussed, and proposals are made for the better post-war society within which the new medical services will have to be built. Methods of payment for health services, on which the Commission's report scarcely touches, are dealt with in detail, even to the formulation of a national balance-sheet.

Footing the Bill

The proposal of Medical Planning Research is that every person in receipt of earned or unearned income should compulsorily pay a social security insurance contribution to the extent (except in the case of the lowest wage-earners) of 8% or 10% of income. In return he would be provided with complete treatment for all forms of sickness, including rehabilitation, special prophylactic measures, advice and supervision for himself and his dependants, cash sickness and unemployment benefits, adequate old age pension, family allowances, and burial allowances, all without means-test. A voluntary increase of, say, 25% in the payment would entitle the contributor to receive an extra degree of privacy in institutional treatment.

It is considered that this form of payment is without the disadvantages attaching to the customary methods of paying fees direct, local rates, charitable contributions to hospitals, and forced payments such as those exacted from employers for workmen's compensation. The present insurance or panel system has advantages and disadvantages which may be set out as follows:

Advantages	*Disadvantages*
Free choice of doctor, even though "largely illusory"	Levy from employers is a tax on industry.
Weekly payments by patient, a factor in retaining self-respect	Cash and other benefits by different approved societies extremely unequal.
Cost of sickness borne while patient is fit.	Approved societies a wasteful form of administration.

The most serious disadvantages of the National Health Insurance system are that it does not cover dependants or the upper and middle income groups, and that it does not provide specialist or institutional treatment. But these are limitations in scope rather than inherent defects.

The health and social service scheme put forward by the Research is estimated to cost 1,000 million pounds (about one-quarter of the present war expenditure). The social security contribution would yield about 300 millions, and the remainder would have to be met by a direct contribution from the Exchequer—that is, by taxation. Income tax is the fairest method of collection of payment, but the reason why the whole sum should not come directly from the Exchequer is that the contribution of the income-tax payer is not connected in his mind, as this social insurance contribution would be, with the services he receives in return; moreover, it is undesirable that the administering body for the health and social services should be under detailed Treasury control.

Central and Regional Machinery

A corporate body, to be called the National Health Corporation, and not a Department of State directly under a Minister of the Crown, is favoured as the central authority for a national organized health service. The Medical Planning Commission left those two alternatives an open question. The Research holds that the corporate body is preferable because: (1) "Parallelism" (that is, division of authority among many persons of equal rank) is possible in a corporate body to a high degree; whereas in Departments of State hierarchical organization, which is to be deprecated, is the rule. (2) Medical policy is long-term, and to submit it to frequent inquisitions by Parliament is to discourage planning and initiative. (3) The principle that the best possible health services should be available to all is not a political issue. (4) Maintenance of health is a joint task for technician and layman; in a Government Department the technician would be under the layman.

The powers of the National Health Corporation would be vested in a board of governors, say three medical and three lay, with a lay chairman—the Commission's view is that such a body should be "predominantly medical" in composition—appointed by the Privy Council on the advice of the Prime Minister and Minister of Health. To the Ministry of Health the corporation would be linked in much the same way as the B.B.C. was formerly linked to the Post Office. The principal executive officer—the director-general—should be, preferably, a medical practitioner. Advisory bodies, their members co-opted by the board, might be nominated by the Royal Colleges, the British Medical Association, the General Medical Council, the universities, nursing bodies, Government Departments, trade unions, and organized industry.

It is further proposed that the corporation should have an administrative office in each of, say, twelve regions in which Great Britain would be divided. The senior officer in each region would be, generally, a medical practitioner. The task of the regional organization would be to see that the medical needs of the population were met and that those working in the health services fulfilled the authorized standards. If regional authorities with elected councils should supplant the present councils of counties and county boroughs, these authorities should be closely linked with, but should not control, the regional organization of the National Health Corporation. In the smaller areas it is proposed to set up local health committees to reflect local sentiment about health problems to the corporation.

"The Home Doctor"

The medical profession is considered by Medical Planning Research in three categories: the home doctor (the general practitioner), the specialist or consultant, and the social doctor (medical officer of health). The home doctor must be of the patient's choice, must be available at or near the patient's home, must give the same standard of advice and skill to all his patients, must be aware when he has reached the limits of his skill and knowledge and refer the case to a specialist, and must be able to arrange appropriate institutional treatment, himself playing an active part in such institutional treatment. He must be an expert in general bedside diagnosis and home treatment, simple clinical pathology, minor surgery and medical first aid, ante- and post-natal care, possibly midwifery, and certainly child welfare. Further, he must be a free man—free, among other things, to refuse to accept a patient (though, having accepted, he must carry through his obligations), free to increase his practice so far as efficiency allows, and free from undue bureaucratic interference.

Remuneration, off-duty times, equipment, and opportunity for acquiring special skills must be adequate. Vacant practices should be filled, after public advertisement, by a small board comprising representatives of the national health service, the regional medical advisory committee, and the local medical committee of the health centre. Patients on the list of a retired or deceased doctor should be invited to choose a new doctor from those working at the centre, including the newly appointed practitioner. Each doctor working at a health centre would accept patients up to a prescribed maximum. His remuneration would consist of a basic salary, a capitation fee, fees for special clinics, etc.—all paid from corporation funds—and private fees for patients choosing to be outside the service. Practitioners entering the service from existing private practices would be granted non-contributory retirement and death pensions in compensation for loss of capital. Sale of practices would not be permitted. The suggestions of Research for the organization of health centres follow closely the scheme for the model centre in the Medical Planning Commission's interim report.

Specialist and Hospital Services

The memorandum of the Research then turns to the question of hospital and specialist services and lays down in detail what such services should provide—consultation in clinics near the patient's home or consultation in the patient's home, out-patient treatment for conditions beyond the scope of the home doctor, in-patient investigation and treatment, rehabilitation, training of doctors, nurses, and ancillary workers, and research. After pointing out the defects of the present system, it defines a national hospital service, the whole cost of which would be borne by the corporation. Like the M.P.C., the Research takes the region as the unit. Each unit would have three or more key hospitals—large voluntary or municipal hospitals or new hospitals—at least one of which should be linked with a university. Attached to each key hospital would be a number of local hospitals or medical centres (existing cottage or municipal hospitals, but greatly altered in structure and function), and around each medical centre would be the local health centres. Each medical centre would have an out-patient department or polyclinic; beds (private and public) for acute cases, minor illness, midwifery, infectious fevers, and chronic sick; a pathological laboratory and radiological department; and a hostel for children of local women admitted as patients. The key hospital would be a complete functional replica of the medical centre, and would resemble in its internal organization a voluntary hospital. Like the Commission, the Research recommends the setting up in every hospital of a committee of the medical staff, but the latter would include representatives of juniors and even of clinical students. It does not favour special hospitals, save the relative few which would act as national centres for postgraduate teaching and research.

As for staffing, all senior appointments should be advertised, the primary selection should be made by the medical committee of the key hospital concerned, and the final appointment by a board composed of members of the regional advisory committee and of specialists in the subject, with, possibly, additional assessors. Junior appointments should be recommended by the medical committee and confirmed by the regional office. It is laid down that no member of the senior staff should be confined to out-patient work, or, indeed, to work at the medical centres or to domiciliary consultation, and none should be free from it.

Senior staff should have the option of part-time or whole-time appointment, and part-time officers should be permitted privately to see "uninsured patients."[1] It is thought that if such consultations are permitted at hospital "the pseudo-consultants will be left alone in Harley Street, which will soon cease to have any cachet." Remuneration for whole-time seniors: £1,500 to £2,000; those serving three-quarter time, two-thirds of the whole-time salary; those serving half-time, one-third of the salary. This reduced basis is suggested because men are likely only to choose part-time work if they see a prospect of greater earnings. For junior appointments little alteration in the present procedure is proposed.

Finally, there is the question of the "social doctor" or medical officer of health, who, it is thought, should operate from an office in each medical centre over an area covered roughly by the attached group of health centres. In addition to his preventive work, he will organize vital statistics and medical intelligence service, incidentally taking over the function of the registrar and receiving all notifications of births, marriages, and deaths. His present duties with regard to food and drugs, housing, and sanitation will continue, and his conditions of service will be identical with those of senior officers at key hospitals.

---

[1] All persons will be insured under the scheme. This reference apparently relates to a provision whereby persons earning over £500 a year will be permitted to opt out of one-eighth of their contribution, and become no longer entitled to medical benefit—one way of preserving a remnant of private practice.

WEEKLY POSTGRADUATE DIARY

British Postgraduate Medical School, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m. Medical Clinics, Surgical Clinics and Operations, Obstetric and Gynaecological Clinics and Operations. *Daily*, 1 30 p.m. Post-mortems *Mon.*, 2 p.m., Ear, Nose, and Throat Clinic. *Tues.*, 10 a.m., Paediatric Clinic; 11 a.m., Gynaecological Clinic; 2 p.m., Genito-urinary Clinic *Wed.*, 11 30 a.m., Medical Conference. *Thurs.*, 2 15 p.m., *X*-ray Demonstration on Radiology in Pregnancy, by Dr. E. J. E. Topham; 3 p.m., Dermatological Clinic. *Fri.*, 12 15 p.m., Surgical Conference; 2 p.m., Gynaecological Conference; 2 p.m., Sterility Clinic.

Fellowship of Medicine, 1, Wimpole Street, W.—*West End Hospital for Nervous Diseases:* Tues and Fri., 3 p.m., M.R.C.P. course in neurology. *King Edward Memorial Hospital:* Sun., 10 a.m. to 12 noon, F.R.C.S. clinical and pathological course (limited to 6) *London Homoeopathic Hospital:* Wed afternoon, F.R.C.S. clinical demonstration (limited to 6) *Hillingdon County Hospital:* All day Sat and Sun., March 13-14. F.R.C.S. week-end course in clinical surgery (limited to 10) *National Hospital for Diseases of the Heart:* Tues and Wed., 10 a.m., Out-patient clinics

Edinburgh Postgraduate Lectures.—At Edinburgh Royal Infirmary, *Thurs.*, 4 30 p.m. Dr. A. F. Hewat: Spontaneous Pneumothorax

DIARY OF SOCIETIES & LECTURES

Royal Society of Medicine.—*Tues.*, 2.30 p.m. Section of Psychiatry; 5 p.m. Section of Therapeutics and Pharmacology. *Wed.*, 2 30 p.m. Section of Proctology, at St. Mark's Hospital, City Road, E.C. *Fri.*, 2 30 p.m. Clinical Section, at London Hospital; 2 30 p.m. Section of Ophthalmology

B.M.A.: Branch and Division Meetings to be Held

Belfast Division.—At Whitla Medical Institute, Belfast, Thurs., March 11, 4 15 p.m. Consideration of the motion on the Beveridge report published in the *Supplement* of Feb. 13, and instruction of Representatives to Special Representative Meeting on March 31.

Brighton Division.—At Royal Pavilion, Brighton, Sun., March 7, 3 p.m. Consideration of the motion on the Beveridge report published in the *Supplement* of Feb. 13, and instruction of Representatives to Special Representative Meeting on March 31 At Lady Chichester Hospital, Hove, Thurs., March 11, 3 p.m. Clinical meeting

Chester Division.—At Royal Infirmary, Chester, Sun., March 7, 4 p.m. Agenda: To consider the attitude of the profession to the Medical Clauses of the Beveridge report. Medical men and women serving in the Forces are cordially invited to attend.

East Suffolk Division.—At East Suffolk and Ipswich Hospital, Ipswich, Wed., March 10, 3 30 p.m. Agenda. Consideration of the motion on the Beveridge report published in the *Supplement* of Feb. 13, and instruction of Representatives to Special Representative Meeting on March 31, etc. All practitioners in the area of the Division are invited to attend.

Glasgow and West of Scotland Branch.—At Institution of Engineers and Shipbuilders in Scotland, 39, Elmbank Crescent, Glasgow, Tues., March 9, 3 30 p.m. Prof. J. M. Mackintosh. Medicine and Town Planning.

Isle of Wight Division.—Joint meeting with Isle of Wight L.M. and P. Committee at Unity Hall, Newport, Wed., March 10, 3.15 p.m. Agenda: Consideration of the motion on the Beveridge report published in the *Supplement* of Feb. 13, and instruction of Representatives to Special Representative Meeting on March 31, etc.

Westminster and Holborn Division.—At B.M.A. House, Tavistock Square, W.C., Thurs., March 11, 5 p.m. Agenda: Consideration of the motion on the Beveridge report published in the *Supplement* of Feb. 13, and instruction of Representatives to Special Representative Meeting on March 31, etc. All practitioners in the area of the Division are invited to attend.

TOWELS FOR DOCTORS

Doctors may now claim, for professional purposes only, a special ration of towels for the period to Dec. 31, 1943. The special ration is four coupons. These are available to specialists, consultants, and general practitioners in private practice, but not to doctors working in institutions or under local authorities, since towels will be provided for them by their employers. Practitioners are particularly urged not to apply for their ration until new towels are genuinely needed.

This special ration will be issued in the form of a coupon-equivalent towel certificate and will be available on and after March 8, 1943. Application should be made to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1. Envelopes should be marked "Towels" in the top left-hand corner, and a stamped addressed envelope *must* be enclosed with each application, otherwise *no* reply will be sent. There may be cases where owing to the size or nature of his practice a doctor may find that, however economical he is, it is impossible for him to manage on the ration allowed. Where this is so a case for special consideration may be stated to the following: in England, the Regional Medical Officer; in Scotland, the Department of Health for Scotland, St. Andrew's House, Edinburgh, 1; in N. Ireland, the Medical Officer, Ministry of Home Affairs, Stormont, Belfast. The supply of towels is now so limited that members of the public must use their own towels more and more and not rely on other people providing them—for example, patients who receive treatment in their own homes or by appointment at surgeries or in private nursing homes will now be expected to provide their own towels.

BIRTHS, MARRIAGES, & DEATHS

BIRTHS

Gimpelson.—On Jan. 13, 1943, at the Lindo Wing, to Lucie (*née* Moskovitz), wife of Lieut. Harry Gimpelson, R.A.M.C. (missing at sea since Dec 6/7, 1942), a daughter—Susan Jill.

Harper.—On Feb 23, 1943, at Hughenden, Limpsfield, Surrey, to Barbara (*née* Pocock), wife of Major Ernest H. C. Harper, F.R.C.S., R.A.M.C. (N. Africa), a daughter.

Jain.—On Feb. 27, 1943, at Claremont Nursing Home, Birmingham, to Grete, wife of Dr. L. R. Jain, a son

McCall.—On Feb. 25, 1943, at Stoke-on-Trent, the wife of Dr. A. J. McCall, twin daughters

Moorhead Hamilton.—On Feb 23, 1943, to Cecily (*née* Brown Kelly), wife of Surg. Lieut.-Cmdr. W. Moorhead Hamilton, R.N., a daughter

DEATHS

Tasker.—In November, 1942, through enemy action at sea, Ronald Henry Tasker, M.R.C.S., L.R.C.P., of the Burmah Oil Company, husband of Mrs. Dorothy Tasker, 5, Darlington Place, Bath, Somerset.

Watterson.—On Feb. 18, at 341, Marine Road, Morecambe, John William Watterson, M.B., C.M.(Edin.), J.P., C.A., Freeman of the Borough of Morecambe and Heysham, in his 80th year.

SUPPLEMENT TO THE

BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 13 1943

GENERAL MEDICAL COUNCIL

DISCIPLINARY INQUIRIES

A special session of the General Medical Council was held on February 17 and 18, and in private on February 19, principally to consider certain penal cases which had been left over from the November session. The only other business was the consideration of a memorandum of evidence proposed to be offered to the Inter-departmental Committee on Medical Schools (the Goodenough Committee); this took place *in camera*. Mr. H. L. Eason presided.

Misleading Certificate: Erasure

The first case was that of James Jackson Brown, registered as of Lauriston Road, South Hackney, who was summoned on the charge that he gave the following certificate for use by the person named in connexion with his call-up under the National Service (Armed Forces) Act, 1939:

> "I hereby certify that Mr. [A. B.] of . . . has been a patient under my care for on 2 years. He then had a severe attack of influenza which left him in the post-encephalitic state."

The certificate was dated May 9, 1940, and it was alleged that the patient had not been under Dr. Brown's care for any such period, that the certificate was untrue, misleading, or improper within the meaning of the Council's Warning Notice, and that it was given in order to enable A. B. to evade his liabilities under the Act. Mr. Gerald Howard, K.C., who appeared on behalf of the complainants, the Ministry of Labour and National Service, said that A. B. was a healthy-looking man aged 28, who got into touch with a man named Pell, who said he would assist him to evade military service. Pell took him to Dr. Brown, who handed Pell a letter containing presumably the certificate which was the subject of the charge. On May 10 the medical board placed him in Grade 4, but he was re-examined on July 26 of the same year and placed in Grade 1 and was now a corporal in the Army.

A. B. in evidence said that Pell agreed to help him to evade service, and said that the cost would be £250, which was paid. Pell told him to act as if he was ill, suffering particularly from giddiness. He was sent by Dr. Brown to see a specialist, Dr. Brady, before whom he also acted, and the specialist made a report which was enclosed with the certificate. The witness said that Dr. Brown did not examine him; but later, under cross-examination, he said that he took a specimen of urine, also that he used a stethoscope. He could not recall that he had seen Dr. Brown before this incident. It was true that he had had an attack of influenza two or three years previously, when three doctors attended him, but he could not say that one of them was Dr. Brown.

Mr. Pereira, instructed by Le Brasseur and Oakley, on behalf of the London and Counties Medical Protection Society, appeared for the respondent, and in answer to his questions Dr. Brown said that when Pell, whom he had known for 20 years, brought this patient to him he did not recall having seen him before. Pell, however, assured him that he had treated this young man two years previously for influenza, and he accepted that assurance and did not look up his records. His records had since been destroyed by enemy action, but they were available at that time (May, 1940). He could find nothing wrong with A. B. except that he appeared to be "daft"; he thought that his previous influenza might have affected his brain, and he sent him to a specialist before giving the certificate. He added that a few months later Pell brought him other similar patients, but he refused to have anything to do with them because he had become suspicious of the business.

Mr. Pereira put in two statutory declarations from medical men testifying to Dr. Brown's high character. He mentioned that Dr. Brown was a native of Jamaica and not fully conversant with the English language. This explained the curious wording of the certificate. The phrase "for on two years" simply meant "about two years ago"; it was not intended to imply that A. B. had been under his care for two years. The certificate admittedly was misleading, but it was not intended to mislead. He pointed out some inconsistencies in the statement of A. B., who had said that he had acted in front of Dr. Brown, though not to the same extent as he had done before Dr. Brady. But if there was, as alleged, a conspiracy between Dr. Brown and A. B. to deceive the authorities any such acting in front of the former would be a mere farce.

The Council considered the case *in camera*, and on the public session being resumed the President announced that the Council had found to be proved the fact that Dr. Brown had certified that A. B. had been a patient under his care for about two years before May, 1940, whereas in fact he had not been under his care for any such period, that he did not make any proper professional inquiries before giving the certificate, that the certificate was untrue, misleading, and improper, and that it was given for the purpose of enabling A. B. to evade his liabilities under the National Service (Armed Forces) Act. In respect of the facts so proved, the Council had judged Dr. Brown to have been guilty of infamous conduct in a professional respect, and had instructed the Registrar to erase his name from the *Medical Register*.

A Questioned Certificate

The Council considered the case of Arthur Hilary Clifton Hill, registered as of the Croft House, Rocester, Staffordshire, who was summoned on the charge that in May and June, 1942, he gave six weekly certificates in relation to the duties of an aircraftwoman, stating in each of them that she was suffering from injury to the forearm and was unable to return to her unit, adding in four of the certificates that she was "unfit to travel," whereas on the dates concerned she was not unable to return to her unit nor unfit to travel. The complainants were the Air Ministry. Dr. Hill was represented by Mr. A. Pereira, instructed by Le Brasseur and Oakley, on behalf of the London and Counties Medical Protection Society.

Mr. Winterbotham, the Council's solicitor, said that the aircraftwoman concerned had been, since she was a child, one of Dr. Hill's patients. While home on leave in May, 1942, she injured her forearm, and on the following day was attended by Dr. Hill, who sent her to the Royal Infirmary at Derby for an *x*-ray examination; the radiograph showed that no bone was broken. Dr. Hill continued to give certificates from May 4 to June 8, always mentioning the arm injury as the cause of her disability, but, so far from being unfit to travel, she married and went away on a short honeymoon during this period.

Evidence was given by the aircraftwoman, Mrs. A., who said that she was a member of the W.A.A.F. from March, 1941, until December, 1942, when she was discharged on medical grounds. While at home on leave in May, 1942, she injured her arm, and went to Dr. Hill, who sent her to the hospital at Derby and on her return gave her the first of the certificates to send to her commanding officer. She agreed that on May 25 she undertook an hour's journey in a train, although on that day she had received another certificate stating that she was unable to return to her unit. She had been a patient on Dr. Hill's panel list for some years, and he had attended her in childhood. During the latter part of her leave on this occasion she developed influenza and laryngitis, for which Dr. Hill also treated her, and which accentuated and prolonged her arm disability. She was all the time "more or less run down," and on eventually returning to her unit she was placed in sick quarters for a week, was never placed on full duty again, and was discharged on medical grounds six months later.

Dr. Hill, in the witness box, said that this girl had been his patient during the whole of the time he had been in Rocester. There was a former history of injury to the wrist sustained at school, and for this she attended at Derbyshire Royal Infirmary over a period of six or seven months. When she came to him for the further injury to the same wrist sustained while on leave, the wrist appeared to be very swollen and painful, and she was herself in a very collapsed state. He suspected a fracture and sent her for *x*-ray examination. The report was that she had no bone injury. The arm was placed in elastoplast. He gave her a certificate stating, what was his candid opinion, that she was unfit to travel. Later she had an influenzal chill and laryngitis, and although the arm trouble was improving this delayed her recovery. He fully agreed that he ought to have been more explicit in the certificates and to have said during the later part of the time that she had the influenzal condition, but without thinking, and in the stress of a busy practice, he had continued to give the certificates in the old phrasing. He fully believed that the girl was unfit to make the somewhat difficult journey back to her unit, and if she did undertake journeys, apart from the visit to the hospital, it was without his knowledge and against his instructions. He was not aware that she had been married while undergoing this treatment. Two statutory declarations from medical men in the locality testifying to Dr. Hill's integrity and his care for his patients were put in.

The Council found the facts proved to their satisfaction. The President said that the Council took a serious view of the duty of every practitioner to take the greatest care over the signing of certificates, especially when they had to do with the service of the Crown in time of war. But the Council hoped the warning he had received in being summoned there to meet these charges would be sufficient to remind him in the future of the need for care in the substance of the certificates he wrote, and did not see fit to direct the Registrar to erase his name from the *Register*.

Convictions for Misdemeanour

In the case of James Stewart Macdonald, registered as of Dixon Avenue, Glasgow, who was summoned in respect of two convictions of driving or being in charge of a motor vehicle whilst under the influence of drink, the Council postponed judgment until May, 1944, and said that Dr. Macdonald (who was legally represented but did not personally attend on this occasion) must then be present.

Alan Gray, registered as of Windermere Road, Carlisle, was summoned on the charge that he had been convicted in December last at Greenwich police court of being under the influence of drink while in charge of a car, and, at the same court, of having failed to appear in accordance with a recognizance. Dr. Gray admitted the offence, and pleaded a great deal of domestic trouble at the time, after having been invalided from the Army. The Council found the conviction proved, and ordered the erasure of Dr. Gray's name from the *Medical Register*. Dr. Gray asked whether he could apply for restoration at some future date. The President replied that, in accordance with standing orders, he could apply for reinstatement at any time.

In the case of Walter Campbell, registered as of Jeffrey Street, Edinburgh, who was summoned following a conviction of being in charge of a motor car while under the influence of drink, the Council postponed judgment until May, 1944.

In the case of Donald McGregor Stewart, registered as of Nantymoel, Glamorgan, who appeared following convictions for defiling a wall with urine in a certain public place and, on another occasion, of using indecent language in a public place, the Council also postponed judgment until May, 1944. In this case Mr. A. Pereira, counsel defending the practitioner, made a strong protest against the Council's solicitor, reading to the Council, in presenting the facts of the case, a statement by the police. He said that not the same objection could be taken to a report in a reputable local newspaper, but a police statement was probably nothing more than an extract from a policeman's notebook. The Council, however, allowed the statement to be read.

The Council dismissed a case against Andrew Dorset Harper, registered as of Five Ways, Torquay, who had been found guilty by a general court martial of having absented himself without leave for ten days from the first depot and training establishment of the R.A.M.C.

Felony and Misdemeanour: Erasure

The Council considered the case of Francis Percival de Caux, registered as of Green Street, London, W.1, who had been convicted at the Central Criminal Court in September last of unlawfully using an instrument, or some other unknown means, with intent to procure the miscarriage of eight women, and of conspiring with other persons with intent to procure the miscarriage of a woman. He had been sentenced to five years' penal servitude in respect of the first offences, and two years' imprisonment in respect of the conspiracy, the sentences to run concurrently. Dr. de Caux did not appear, and it had been ascertained from the governor of the prison that he did not wish to attend. The Council instructed the Registrar to erase the name of Dr. de Caux.

E.M.S. PATHOLOGISTS' FEES

On Jan. 16 we published in the *Supplement* (p. 10) the new scale of fees payable to pathologists in the E.M.S. When the Pathologists Group Committee of the B.M.A. met recently it adopted the following resolution:

> That the committee accepts the unusually low unit scale of fees provided for in Circulars 2394 and 2752 in a spirit of contribution to the war effort and emphasizes the fact that these low fees are not intended to apply to work done either for local authorities or for those patients for whom the schedule of fees for pathological work for insured persons and their dependants has hitherto been found to be appropriate.

CERTIFICATES FOR PRE-NATAL ALLOWANCES

The attention of the B.M.A. was recently drawn to the fact that War Office Regulations demanded that the certificate accompanying applications for pre-natal allowance made by the wife of a Service man must be signed by a medical practitioner. The Association, realizing the additional burden thus thrown on the doctor, pointed out to the War Office that this was a case in which the signature of a certified midwife might well be accepted. The following letter has now been received from the War Office, dated Feb. 10, 1943:

> ". . . I am directed to inform you that approval has now been given for the signature of a State-certified midwife to be accepted on the certificate accompanying the application by the wife of a Service man for pre-natal allowance"

The Home Office announces that Dr. Miraj ud Din of Birmingham is not authorized to be in possession of and to supply any drug or preparation to which the Dangerous Drugs Regulations, 1937, or the Raw Opium, etc., Regulations, 1937, apply.

POSTGRADUATE NEWS

The Fellowship of Medicine announces a revision course in anaesthetics, daily, from April 5 to 17. Lectures daily at Royal Cancer Hospital, Fulham Road, S.W. 3 p.m. and 4 30 p.m., and practical demonstrations at various London hospitals

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W—*Daily*, 10 a m. to 4 p m , Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations *Daily*, 1.30 p m., Post-mortems *Mon.*, Course on the Surgical Care of the Soldier in Training begins; 2 p.m., Ear, Nose, and Throat Clinic. *Tues.*, 10 a m., Paediatric Clinic; 11 a.m., Gynaecological Clinic; 2 p m , Genito-urinary Clinic. *Wed.*, 11.30 a.m , Medical Conference. *Thurs*, 3 p m., Dermatological Clinic *Fri.*, 12 15 p m., Surgical Conference; 2 p m , Gynaecological Conference; 2 p m., Sterility Clinic.

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W—*West End Hospital for Nervous Diseases:* Tues. and Fri., 3 p m M R C P course in neurology. *London Homoeopathic Hospital* · Wed afternoon, F R C S clinical demonstrations (limited to six). *Royal National-Orthopaedic Hospital* · Sat , March 20. F.R C S orthopaedic course (limited to six) *National Hospital for Diseases of the Heart;* Tues. and Wed , 10 a m , out-patient clinics. *Radcliffe Infirmary:* Daily lectures and demonstrations, Revision course in anaesthetics.

ROYAL NATIONAL THROAT, NOSE AND EAR HOSPITAL, Gray's Inn Road, W C.—*Fri* , 4 p m Mr J. D. McLaggan. Chronic Suppurative Otitis Media.

DIARY OF SOCIETIES & LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S W.—*Tues.* and *Thurs* , 2 15 p m Lumleian Lectures by Dr. G Evans: Arteriosclerotic Disease.

ROYAL SOCIETY OF MEDICINE —*Tues.*, 4 30 p m Section of Pathology *Thurs* , 4.30 p m Joint Meeting of Sections of Dermatology and of Physical Medicine; 4 30 p m. Section of Neurology *Friday*, 3 30 p m. Section of Obstetrics and Gynaecology; 4.45 p m Section of Radiology

CHADWICK TRUST —At 26, Portland Place, W., *Tues* , 2 30 p m Dr. R. Cruickshank: Some Post-war Problems in the Control of Infectious Diseases

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W—*Mon* , 5 p.m Discussion: Diagnosis and Treatment of Malignant Growths of the Lungs. To be introduced by Dr. Geoffrey Marshall, Mr. R C Brock, and Dr F MacDonald Allchin.

B.M.A.: Branch and Division Meetings to be Held

INVERNESS-SHIRE DIVISION.—At Royal Northern Infirmary, Inverness Sat , March 13, 3.30 p.m Agenda: Consideration of the motion on the Beveridge report published in the *Supplement* of Feb 13, and instruction of Representatives to Special Representative Meeting on March 31, etc. All practitioners in the area of the Division are invited to attend.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thurs., March 18, 7 15 p m. Clinical demonstrations in the Out-patient Department. Address by Prof. J Chassar Moir: The Diagnosis of Pelvic Contractions All members of H M. Forces serving in the area of the Branch are invited to attend

WILLESDEN DIVISION.—At Willesden General Hospital, Sun , March 14, 10 45 a m Agenda: Consideration of the motion on the Beveridge report published in the *Supplement* of Feb. 13, and instruction of Representatives to Special Representative Meeting on March 31, etc. All practitioners in the area of the Division are invited to attend

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s. 6d This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTH

LIDDELL-MILLIGAN.—On March 5, 1943, at Livingstone Memorial Hospital, Dartford, Kent, to Gwen (*née* Higgs, late Sister, P M.R A F N S.), wife of Dr W Liddell-Milligan, St George's Hospital, Morpeth, a son.

DEATH

BODLEY.—On Feb 28, 1943, Dr. Alfred Lang Bodley, surgeon, of West Bromwich, after a long illness, aged 52 years.

SUPPLEMENT TO THE

BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 20 1943

INSURANCE ACTS COMMITTEE OF THE B.M.A.

A meeting of the Insurance Acts Committee was held on February 25, under the chairmanship of Dr. E. A. GREGG. Sitting first as trustees of the National Insurance Defence Fund, they authorized expenditure from the Fund of an amount not exceeding £2,500 in one year for propaganda purposes. On the question of the proposed increase of the target to one million, the chairman said that money was wanted, in all probability "lashings" of money, and this was the time to start to get it. The benefit would be reaped more especially by the younger men—their sons and junior colleagues—but he hoped that older practitioners who had already subscribed for many years would continue to do so.

The Beveridge Report

The committee then considered the recommendation which the Council of the Association proposed to submit to the Special Representative Meeting called for March 31. It was noted that the recommendation, which was drafted, of course, before the recent debate on the Beveridge report in Parliament, made the Association's willingness to co-operate conditional upon the acceptance of the assumptions and proposals of the Beveridge report "taken as a whole," whereas the Government had not taken them as a whole: it had adopted parts of the scheme, rejected others, and had said nothing about many more. The chairman pointed out that if the Government had picked out of the scheme the proposals for a comprehensive medical service and had left the rest alone, the position would have been fundamentally altered; but he did not interpret the recommendation as meaning that every detail suggested in the report must be accepted before the recommendation became operative. There did not seem to have been a departure of such a character as to justify the abandonment of the recommendation, but it would be for the Representative Meeting and Panel Conference called for the same date to amend the recommendation, if desired, in the light of what the Government had announced.

The Secretary (Dr. Anderson) reported that he had received a letter from the Secretary of the Ministry of Health asking for the appointment of representatives of the profession to consult with the Minister on future medical services. The Association Executive had drawn up a list of those who would meet the Minister on March 9 to hear what he had in his mind. This would be a preliminary meeting only, and a report would be made to the Joint Conference on March 31. The body to represent the profession for this purpose on March 9 included the principal officers of the Association, the chairmen of the I.A.C. and of the Panel Conference, the chairmen of several of the Association committees, representatives of the Royal Colleges, the Society of Medical Officers of Health, and the Medical Women's Federation, and others, as well as certain additional representatives in the event of the conversations covering Scotland. Ten of the persons on the list were general practitioners, seven of whom were members of the I.A.C.

The committee had before it a communication which the Hampshire Local Medical and Panel Committee had addressed to peers and members of Parliament in its county; it consisted of resolutions passed by the committee declaring that the proposal for a free medical service as outlined in the Beveridge report was prejudicial to the interests of the medical profession. The I.A.C. agreed that a letter be sent to the Panel Committee concerned and to all Panel Committees deprecating individual action of this kind without consultation.

The Capitation Fee

The chairman reported that at the last meeting of the Council he had explained the circumstances under which the application for a wartime increase in the insurance capitation fee had been made and its rejection by the Minister. Two members of the Council who were consultants, one of whom said that he had never spoken in the Council on insurance matters before, proposed and seconded a resolution, which was carried, deploring the Minister's rejection of this entirely reasonable and justifiable claim. A letter which the Executive Committee had sent to the Minister recapitulating the main points of the argument, and expressing regret at his decision, which, it said, it could not regard as final, was approved by the full committee. The consideration of a proposal that a request be now made for arbitration was postponed until the next meeting of the committee.

Correspondence with the Minister

The following is the text of correspondence with the Minister of Health, following a deputation from the I.A.C. on Jan. 4:

Letter from the Minister of Health, dated Jan. 20, 1943

"I have been thinking over the representations made to me by the deputation from the Insurance Acts Committee of the British Medical Association, which called on me on Jan. 4, and in your subsequent letter of Jan. 8.

"The deputation stressed again the 'shift of risk' among the insured population brought about by war conditions accompanied as it has been of late by an increase in short-term sickness. You will remember that in my reply I said that the increase of the work of doctors caused by these circumstances was recognized and taken into consideration when my previous decision was conveyed to you on Oct. 17 last. Some measure of that increase has, as you know, now become available and you refer to this in your letter of Jan. 8. It does not, however, appear to me that the ascertainment of the increase affects my argument that it is contrary to Government policy, in such circumstances, to recognize additional work as establishing a case for what is in effect a war bonus, and I regret that I cannot vary the decision already communicated to you.

"I have fully considered the suggestion that the additional remuneration should be given by way of a post-war credit, but I am afraid that this offers no solution. A postponement of the payment does not affect the general principle which, as I have already indicated, the Government have felt bound to adopt.

"The deputation stressed the importance of the Protection of Practices Scheme as a valuable aid in the recruitment of doctors for the Forces. While I recognize the value of that scheme, I do not think that it creates a situation in which I could properly ask that the Government's general policy should be altered in this particular instance.

"As stated in the previous letter of Oct 17 last, I regret having to come to this decision, which must, I fear, so long as present circumstances obtain, remain final"

Letter to the Minister of Health, dated Feb. 12, 1943

"The Insurance Acts Committee has considered your reply of Jan. 20 to the representations made to you in recent months, and in particular to the representations made to you on Jan. 4 and in the Secretary's subsequent letter of Jan. 8.

"In your reply you rightly state that the deputation stressed again the shift of insurance risk among the insured population brought about by war conditions, though you go on to state that these circumstances were recognized and taken into consideration in your letter of Oct. 17 last. The committee has re-examined your letter of Oct. 17 and can find no recognition or admission of the fact that there had been an increase of work as the result of a shift of insurance risk. Indeed, your letter of Jan. 20 is the first frank admission of the fact of increased work, an admission which you could hardly fail to make in view of the statement of the Government actuary, which was made known to us only at the end of our meeting with you on Jan. 4.

"The committee did and does stress this point as being the main basis of its claim. Insurance doctors are participating in an insurance medical service, and when the insurance risk so shifts, as the result of war circumstances, as to increase the burden of work falling upon them they are justified in claiming a proportionate increase in their remuneration. The committee is not satisfied that you have in fact given any weight whatever to this argument, which is now admitted by you for the first time to be sound Having admitted it, you go on to assert what appears to the committee to be a statement regarding Government policy which is inconsistent with the facts So far from it being an axiom of Government policy that increased work should not be rewarded by increased pay, it is the widespread practice in this country, by undertakings both Governmental and commercial, to give such increases or make them possible, as, for example, by overtime payments or piecework rates.

"When you put forward the argument that it was contrary to Government policy to award cost-of-living bonuses to the higher income groups we did not demur to your statement, unwelcome though it was But when you extend the argument so as to deny a group of men undertaking increased work as a result of wartime circumstances the remuneration which is their due, you interpret Government policy in a way suitable to your argument but inconsistent with its application throughout the country.

"The committee is not satisfied with your replies on the Protection of Practices issue, as what was proposed was not an alteration of the 'Government's general policy' but an application of it.

"In the latter part of the Ministry's letter of Oct. 17 it is stated that it is desired to assure the committee 'that the decision will in no way prejudice future discussions which the Department may have to enter into on wider matters affecting the medical profession.' In actual fact, this decision, by accentuating the dissatisfaction of a large body of general practitioners with the remuneration of the service for which you are responsible, will inevitably affect the attitude of the medical profession as a whole in future negotiations.

"That the attitude of the Insurance Acts Committee is shared by the profession as a whole is evidenced by the following resolution passed by the Council of the British Medical Association at its meeting on Feb. 3:

> "'That the Council deplores the rejection by the Minister of Health of the reasonable and justifiable application by the Insurance Acts Committee for a war-time increase in the insurance capitation fee.'

"You know perfectly well that the Insurance Acts Committee is deterred by considerations of national interest from advising insurance practitioners to withdraw from their insurance contracts at present. But for such considerations of national interest the Insurance Acts Committee would, indeed, advise that step, so deep and so widespread is the dissatisfaction within our ranks. The committee cannot escape the conclusion that you are taking advantage of the public-spirited attitude of insurance practitioners in this matter.

"The committee cannot regard your decision as final, and is now considering what other steps it should take."

Reply from Minister of Health, dated March 5, 1943

"Mr. Brown has asked me to write to you in reply to your letter of Feb. 12 about the capitation fee under the National Health Insurance Acts. Mr. Brown has been thinking over what you say in your letter, but he had had in mind all the considerations you set out when he wrote his letter of Jan. 20 to Dr. Anderson, and, as he said at the end of that letter, the decision which it conveyed must be regarded as final."

The Insurance Acts Committee is considering the next step.

Other Matters

A report was made on a number of matters which had lately been the subject of conversation with representatives of the Ministry. Sympathetic consideration had been promised by the Ministry of a proposal to grant sickness benefit to an insured woman who, during the last weeks of pregnancy, was certified to be unfit for work on account of pregnancy alone. Another question raised was as to the amount included in the Central Practitioners' Fund in respect of juvenile contributors and generally as to the constitution of the Juvenile Deposit Contributors Fund. It was stated that the Government actuary was preparing a memorandum on the subject.

On a communication from one of the Group Committees urging that every endeavour should be made to keep doctors on Service fully informed of all important decisions and of negotiations affecting practitioners, the chairman said that this was the full intention of the committee so far as lay in its power. The obvious medium for such information was the *Supplement*.

After inquiry on a representation by the West Ham Insurance Committee the Minister of Health has decided not to remove the name of Dr Dinshaw Framroze Tarapore of 11, Forest Road, Forest Gate, E.7, from the medical list of the insurance committee Dr. Tarapore is to pay £20 towards the costs of the committee

---

PLANNING FOR RADIOLOGY

The Faculty of Radiologists, eager to ensure the proper equipment of and opportunity for radiology among specialist services in future medical planning, has put forward in two pamphlets its recommendations for the distribution and organization of radiotherapeutic centres in Great Britain and also for the provision of a radiodiagnostic service.

Treatment Centres

For radiotherapy the Faculty urges the aggregation of small departments into large centralized units. The many advantages of such aggregation include the maximum use of specialists and the improved facilities for training in the subject. Clinical progress in radiotherapy would also be assisted by close association of the department with a large medical centre. The desirable unit to aim at is a department capable of treating 1,000 new cancer cases per annum. This number might be expected to be forthcoming, in the absence of any other treatment centre, from a population of 2,000,000. The staff of such a unit should include five radiotherapists, two physicists, eleven technicians (including specially trained nurses), together with clerks, almoner, and ordinary nurses. It should have at its command seven *x*-ray therapy plants, of which at least four should be for deep therapy, and two grammes of radium, made up in tubes and needles, excluding beam unit radium. The number of beds should be at least 65.

It is considered that London, with the Home Counties and Sussex, with a population of 12,500,000, should have six such radiotherapy departments. At the present time there are at least 30 hospitals in London which claim to provide a radiotherapeutic service, but even among the teaching hospitals there are few with radiotherapy departments approaching the standard here laid down. The various teaching and cancer hospitals in the London area are therefore brought into six suggested groups for this purpose. In the Provinces the greater part of the country could be served by a department, specialized hospital unit, or control organization for each of the ten teaching schools. In some areas, such as Devon and Cornwall, centres apart from medical schools might be necessary. The main radiotherapeutic centres in Scotland should be at Edinburgh, Glasgow, Dundee, and Aberdeen.

Radiodiagnostic Services

For diagnostic clinics different considerations apply. These clinics should be numerous and cover an area systematically. At present there are between 800 and 900 *x*-ray diagnostic departments in hospitals in England and Wales, but efficiency is not achieved unless the department is under the supervision of an experienced radiologist of consultant status. Every department should have at least one properly trained radiographer working under the radiologist; the services of a whole-time man or woman could be utilized in any department having a turnover of 2,000 cases a year. Departments in key hospitals should be equipped completely and be able to undertake the most difficult types of work. Intermediate hospitals should be able to handle all routine general radiological work. In cottage hospitals equipment should vary according to locality; if they are near larger hospitals they need be equipped only with small apparatus suitable for casualty work. A questionary recently addressed to its members by the Faculty showed that an overwhelming majority was in favour of payment by salary for hospital work, and there was a large majority in favour of concentrating all *x*-ray diagnostic work, including private work, in hospital. Only a small minority preferred a whole-time salaried hospital appointment without the right to see private patients.

In the view of the Faculty radiologists should be appointed by the regional body controlling and co-ordinating hospital services and should be appointed to the region, although in practice divisions of the region would make their own appointments and submit them for approval. The staffing of the regional scheme should be such that divisional hospitals could serve those hospitals in the division too small to support a radiologist of their own. It is regarded as of critical importance that properly trained and qualified radiologists should run the service, and the Faculty welcomes the suggestion that a joint committee of the Royal Colleges should decide on consultant status.

BOOKS FOR PRISONERS OF WAR

The B.M.A. has arranged for gifts of medical books to be sent to certain camps and hospitals for prisoners of war in Germany where numbers of its members are known to be. Little exact knowledge, however, is available of the special needs of the various camps for medical literature. Individual prisoners who are members of the Association are therefore invited to write to the secretary, specifying the particular books which they would like to have, either for use in connexion with the medical care of fellow-prisoners or for the purpose of private study. The Association will gladly make every effort to supply their needs.

MEDICAL WAR RELIEF FUND

FORTY-THIRD LIST

Amount previously acknowledged—£48,300 19s 7d and £100 3½% Conversion Stock and £40 3% Defence Bonds

Individual Subscriptions

£10 10s.—Dr H F Hugo, Crediton (3rd donation).

£6 6s.—Dr C. M. Cusden, Iver (4th donation).

£5.—Lady Hurst, Chislehurst.

£2 2s.—Capt. N. Bickford, R.A.M.C. (7th donation); Dr. A MacFaul, Leigh, Lancs (2nd donation); Dr. E. Muriel F. McLean, London; Dr R. B. O'Brien, London.

£1.—Dr. A. L Cowan, Glasgow

£53 13s. 9d. ($240.00).—Canadian Medical Association (amount already sent, £1,433 18s. 10d); Saskatchewan Division, $40.00 (2nd donation); Tisdale Clinic, Saskatchewan, $50.00; Dr. J. A. Mathewson, Saskatchewan, $10 00; Brant County Medical Association, Ontario, $50.00; Victoria County Medical Association, Ontario, $50.00 (4th donation); Drs O. M. Irwin and R R. Stirrett, Saskatchewan, $25 00; Dr. H Levson, Saskatchewan, $15 00.

£10 10s.—Plymouth Division—per Dr. Mabel L Ramsay (amount already sent, £323 7s 6d); Mr H F. Vellacott (5th donation)

£2 2s.—Exeter and District practitioners—per Dr W. A. Robb (amount already sent, £205 2s); Dr D T. Mackie (2nd donation)

£1.—Lincoln Division—per Mr. G. A. Bagot Walters (amount already sent £327 11s); Dr T. W. A. Daman.

Local Medical and Panel Committees

£5.—Norfolk (3rd donation).

Total—£48,404 9s. 4d. and £100 3½% Conversion Stock and £40 3% Defence Bonds.

Cheques, payable to the Medical War Relief Fund, should be sent to Dr. G. C. Anderson, Honorary Treasurer of the Fund, British Medical Association House, Tavistock Square, London, W.C.1.

Correspondence

Unbacked Negotiations

SIR,—Unbacked negotiations are doomed to fail. At a recent A.R.M. deep-felt dissatisfaction with the result of the negotiations in respect of the capitation fee for N.H.I. was expressed, as well as criticism and censure of those who conducted the negotiations. The fact that these criticisms were misdirected does not diminish the prevailing spirit of discontent. We are now likely to be faced with more vital negotiations affecting the whole profession, and already there is a feeling of frustration and defeatism. I have heard such expressions as "the same old gang" used to indicate those likely to conduct the negotiations, and the expression "selling us to the Ministry" to show what is likely to be the result. Even supposing that the Council of the B.M.A. does appoint members out of touch with actual practice and remote from the periphery to represent us, are they entirely to blame if negotiations fail? Has the Association considered what would happen if we refused the terms offered? Surely this is the crux of the whole matter. Unless some scheme is prepared in advance to meet such an eventuality we are as powerless as, for instance, the Danes were before Hitler. If we refuse, what then? Now is the time to consider this.

The history of collective bargaining in this country has clearly established the right to strike, and the Labour Party should be the last to deny this necessary weapon. The idea of a doctors' strike is abhorrent to all doctors. It is inconceivable that we should deny our services to the sick and refuse to relieve their sufferings. Moreover we have no strike funds. But is this the only alternative? I think not. It should be possible to work out a scheme of fees to insured persons if the doctors resign *en masse* from the panel and Government service. Panel cheques are payable in arrear, so that every panel doctor would be entitled to a quarter's income on resignation for the work already done. This would provide a start. Fees would then be charged to all insured persons who could afford to pay, and this at the moment would include the vast majority. The rest would have to be treated for nothing, as has often been done before by our profession.

The resulting inconvenience and chaos affecting both patients and the Government would prove a formidable weapon. It might be argued that this is not the time to embarrass the Government, to which I would reply that this is also not the time to exploit the profession, and that it takes two to make a quarrel. The Government might attempt to stampede or defeat us by trying to introduce a whole-time service; but this could equally well be resisted by the same methods, and by "black-listing" all appointments in such a service. The "black-listing" of certain public appointments has in the past been one of the most successful efforts of our Association.

The success of any attempt to resist what we consider unjust terms would depend upon: (*a*) the efficacy of any alternative scheme, (*b*) the loyalty of the profession in backing the scheme, and (*c*) the support afforded by the public enlightened by a suitable campaign of information. To secure the greatest measure of support efforts should be made to draw up the scheme with other organizations of doctors, and to obtain their support so that a united front could be maintained. It might involve sacrifices on the part of doctors, but no battle can be won without sacrifices, and the miners and other workers have demonstrated that if members are determined and willing to accept sacrifices to secure justice much can be achieved. Can we expect such loyalty in our profession? Otherwise negotiation becomes a farce and the negotiators, however able, merely representatives to receive "the terms of surrender." It is a matter of the greatest urgency that our representatives should be fortified with the assurance that, if the terms offered are such that they cannot recommend their acceptance, an alternative to surrender does exist.

We must face facts and think rationally. It is thought that the medical service part of the Beveridge plan may be the only part to be adopted for a time. Why? Because the medical profession is easily coerced and is more easily tackled than some of the other and more powerful interests concerned with other parts of the plan. Surely this alone is the strongest indication of the weakness of our position in negotiation and the urgent need for remedying our defences. Now is the time to prepare a scheme or it will be too late. I am entirely in favour of the principle of the Beveridge report, and welcome its introduction provided that the broad plan is accepted (except for minor details) and that satisfactory terms and conditions are offered to the medical profession in return for their co-operation and surrender of certain private interests. My anxiety concerns the nature of the terms and conditions, and the weakness of our position in negotiation.—I am, etc.,

Hove. H. J. MCCURRICH.

State Service and Private Practice

SIR,—Surely it would be deplorable when we are fighting a war for democratic ideals that medical men should carry on a campaign to protect medical vested interests and encourage snobbery, lay and medical. I refer to section (*b*) of the motion to be considered at the B.M.A. Representative Meeting on March 31. We may say we are not intending to do any of these things, but the public won't believe us. I therefore appeal to those who will be present at the meeting at B.M.A. House to ponder well over this question, and to consider whether it might not be best for a great profession to throw in its whole weight to make the State scheme a great success, remembering that prevention of disease must be the prime endeavour—an endeavour which would not be greatly promoted by getting extra money for work outside the State scheme. Our brothers on the various fronts will think all the more of us at this critical time if we put the national interest above any private one.—I am, etc.,

E. H. M. MILLIGAN,
Glossop. M.D., D.P.H.

New Hospital Provident Scheme for Londoners

SIR,—In the paragraph under this heading (*Supplement*, Feb. 20, p. 27), after saying that members of the middle classes often find it difficult to meet the cost during illness of the private ward in a hospital or nursing home, you go on to say that there has been no provident scheme to enable them to insure against this. I am sure you will be glad to correct the error into which you have fallen, because for 21 years there has been in existence the British Provident Association, which has been doing this with a considerable amount of success—a success which would have been much greater if the medical profession had backed it as I always hoped they would. I was on its executive for some years, and it was very gratifying to see the way in which it was appreciated by many of the "new poor." And it lacks one disadvantage which the new proposed scheme has, that of being confined to the London metropolitan area. The B.P.A. also has the advantage over the new scheme that it does make a considerable grant towards preliminary consultation fees. It is a pity, I think, to ignore the good work that has been done by this body, and I should like to bring it to the notice of doctors not only in the London area but all over the country. They would find it of great help to a class of patients which wants to pay its way but would have difficulties without some such arrangement as this. The President of the B.P.A. is the Earl of Harewood, and the secretary Mr. T. Denman. Doctors who are interested would be well advised to write to 30, Lancaster Gate, London, W.2, for particulars. I am not writing this in any spirit of opposition to the new scheme. There is room for both.—I am, etc.,

London, W.C.1. ALFRED COX.

Planning by the Doctor's Wife

SIR,—I imagine that there are no women who live so closely in contact with, and whose private lives are so affected by, their husbands' work as G.P.s' wives. May we not therefore be allowed to help in planning for the future? As the wife of a man with a busy industrial practice, I have lived for many years among my husband's patients, away from my friends, in an area where it is impossible to send my children to school. I am fortunate in having a modern house, though we have only a very small garden, but many G.P.s are forced to live in large old houses, difficult and expensive to run, because in the areas in which they practise these are the only type having the necessary reception rooms. If our husbands were able to do their work at a health centre, it would then be possible for us to live, as do other professional men and their families, in pleasant surroundings where a normal social life is possible. Is it not time that we, as G.P.s' wives, insisted that we do not spend the rest of our lives living "over the shop"?—I am, etc.,

Birmingham. P. M. BEAUCHAMP.

The Monetary Value of Practices

SIR,—Much has been written in your columns for and against a fully controlled State Medical Service, and undoubtedly much has been learnt from the various arguments that have arisen. It appears to me that one vital point has been left practically undiscussed—viz., the fate of the doctor's practice as regards its monetary value. The majority of practices have been bought and years of hard work put in to pay off the debt incurred. This is, in most cases, the doctor's only asset.

I believe it has been suggested that the doctor in a State-controlled medical service should receive a pension on reaching an age limit. This is all very well, but would the pension, in the event of his predecease, be carried on to his widow and/or his dependants? It occurs to me that in the event of the adoption of a State-controlled medical service it should be made a condition of acceptance by the profession that existing practices are bought by the Government at the rate at present operated by the British Medical Bureau.—I am, etc.,

Braintree, Essex. L. C. J. EDWARDS.

Vaccination

SIR,—May I endorse what Dr. A. K. Thomas (*Supplement*, Feb. 20, p. 27) has written concerning the unsatisfactory state of affairs in public vaccination? In one way my experience has been happier than his. I also queried the potency of the lymph with which public vaccinators are obliged to work, and I received a very courteous reply from the director of the Government Lymph Establishment, who set before me the figures for the country as a whole and told me that the establishment had to be content if the rate of successful cases was 80% or over. I was able to point out that my own successes had been 100% with every batch which had shown 80% for the rest of the country. More recently I wrote again about my failures with batch 468 and was civilly informed that this had been unsatisfactory.

To be denied payment because of one's lack of success with faulty material is an irritating state of affairs. To be denied it because of failure in immune persons is maddening.—I am, etc.,

DONALD M. O'CONNOR.

UNUSED PETROL COUPONS

It is understood that doctors called up for military service often fail to return their unused petrol coupons. Doctors generally are reminded that any unused coupons should be returned to the Regional Petroleum Officer at the end of the rationing period or when a practitioner for any reason ceases to practise.

H.M. Forces Appointments

ROYAL NAVY

Surg. Lieut.-Cmdr. J. L. S Coutler to be Surg Cmdr.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lieut.-Cmdrs. J. B. Hutchinson, V D, E. L Puddy, R S Allison, R L Stubbs, H P Widdup, H M Willoughby, V D, L D. Nelson, C C. Ungley, A. H. Shelswell, V.D., and A. R. Thomas to be Surg Cmdrs.

Surg. Lieuts L Foster and R. F B. Bennett to be Surg Lieut.-Cmdrs.

Prob. Temp. Surg. Lieuts. R. F Clarke, C. F Donovan, J. E Richardson, D J. O'Brien, N. A. Neville, G E. Mallock, J A. Knowles, N S Marsden, A. J. Drew, C. H. Kitchen, D C. Lillie, and W. Black to be Temp. Surg. Lieuts

ARMY

Col. J. G. Gill, D.S.O., O.B.E., M.C., to be a D.M.S., and has been granted the paid acting rank of Major-Gen

The following Consultants have been granted the local rank of Brig.: Temp Cols J. Biggam, M.C., D. Fettes, O.B.E., and F. M Lipscomb

ROYAL ARMY MEDICAL CORPS

Major (War Subs. Lieut.-Col.) (Temp. Col.) W. J F Craig to be Lieut.-Col

Lieut.-Col L B. Clarke having attained the age for retirement, is retained on the active list supernumerary to the establishment.

Capt W. F. L. Fava to be Major.

TERRITORIAL ARMY, R.A.M.C

War Subs. Major A. G. W. Whitfield has relinquished his commission on account of ill-health and has been granted the honorary rank of Major (Substituted for the notification in a *Supplement* to the *London Gazette* dated Feb. 5.)

Lieut. F. A Macrae, from Seaforth Highlanders, T.A., to be Lieut

2nd Lieut. S. Smith, from R.A., T.A., to be Lieut.

TERRITORIAL ARMY RESERVE OF OFFICERS: R.A.M.C.

Capt R. S. Morshead, M.C., having attained the age limit, has relinquished his commission and retains the rank of Capt.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Capt. D McBain has relinquished his commission on account of ill-health and has been granted the honorary rank of Capt

Lieuts. J. J. McGann and L. S. Davies have relinquished their commissions on account of ill-health and have been granted the honorary rank of Lieut

The notifications regarding Lieut. F. A. Macrae, published in *Supplements* to the *London Gazette* dated March 24 and Sept 29, 1942, are cancelled.

The notification regarding Lieut. S Smith in a *Supplement* to the *London Gazette* dated Jan 1, 1943, is cancelled.

To be Lieuts.: J. McKenzie, R. Bell, W. R. Black, D. S Buchanan, P. S. Buckley, J. F. Dick, L. W. D. Drabble, J. A Flaherty, C. E. Hagenbach, A. Hollingsworth, U M Hopkins, A. Lask, T. J. Peristiany, K J Samson, H S C. Smith, M. Steel, N S. Taylor, G. B. Thrift, A. C. Welch. L. M. Whitaitt, D D. Clarke, W. J. Bremner, L. S Carstairs, T. F Everett, E D. Falconer, C. Fridjohn, A. Georgiadis, J Marshall, G. C. Mackay, J P Milne, A E. Penn, C. E. Powell, A. R Rennie, E. M. Tustin, C Gutman, B. Barnett, A. Bigham, J. Ackerley, W H. Berry, G. E. N. Bird, A G. Brownlie, J P. J. Burns, B. Cimbelmann, H H Cohen, D. J. Cussen, S J. De Navasquez, A. W. R. Eardley, S. Graham, L. Harris, A Heron, R. S. Holcombe, R. D. C. Johnstone, L. I Johnston, A. Lees-Low, S. M. Levy, S. H Lishman, J. C. W. MacFarlane, H. E. S Marshall, H. F Moffit, D. A. O'Sullivan, T N. Parish, H W. Porter, W. G Robertson, T. S Rodgers, T. M. Rowatt, C J Sanderson, J J. Shipman, B. Sidman, P. H D. Stone, G. B T. Story, E C Sugden, W. S. Sutton, J. Symon, T. M. Thomas, J. St. J. F W. Wallace-Collett, R. B. Welbourn, E. W Webster, R. F Boomla, A D. M. Hamilton, J. Harkness, W. C Harvey, J. Jacobs, E T. James M. C. H. Kingdon, J. A. Livingston, I. J. MacCammond, B. Maddison, G. D. Mariano, P J W. Milligan, J. C. V. Murphy, M. Odess, I S Phillips, G A. A. Powell, M Robinson, R M Saleh, D G Vulliamy, D. W. Wilks, J. H. Wood, A C Douglas, J W. L. Doust, R S. Gibson, J Gilchrist, A. B. Hill, J. E. C. Jones, M. J. Kelly, L. Lurie, A. W. Pringle, A. B. Robertson, H N Shepheard, G. F. Shaw, C. H. Sims, P. Strelitz, J. Stuppel.

ROYAL HORSE GUARDS

Lieut. (War Subs. Capt.) J. M. Brown, from R.A.M.C., Emergency Commission, to be Surg. Lieut. (War Subs Surg Capt.).

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

The following M.O.s have been granted commissions in the rank of Lieut.: Mary White, Janet W. Herriot, Christine J T. Jamieson, Robina M Marwick, Stella M. Cutner, Freda C J. Nicoll, Mary G Powell, and Mary W. Taylor.

ROYAL AIR FORCE

Squad Ldr. B G. Haynes has resigned his commission.

Miss M. L. Watson, M.O. with the relative rank of Flying Officer, has been promoted to the relative rank of War Subs. Fl. Lieut.

ROYAL AIR FORCE VOLUNTEER RESERVE

To be Fl Lieuts (Emergency): G. O Horne and D F Kanaar

The notification concerning J. C Garland in a *Supplement* to the *London Gazette* dated Feb. 9, p 707, col 2, should read Fl. Lieut. and not Flying Officer.

Flying Officers J Jacobs, F. G. M Ross, G. R. Davies, J. J S Wilson, J. R M. Vance, G. M. Tucker, R. P Parkinson, D. Aitchison, K. M. Hay, J A J. Wiseman, R. O. M. Jones, C. S N. Swan, T. G Barlow, A. N Pickles, P. A. Killian, C T. B Adams, R. Mortimer, and J. M. B. Morwood to be War Subs Fl. Lieuts.

Flying Officer R N Harbinson has resigned his commission and retains his rank

To be Flying Officers (Emergency): M. S Aldridge, R W. Bailie, G Bates, D. H Bone, H. P. Hughes, E R. Jordan, W. H. Lindsay, J B. H Musgrove, W A. Ogilvie, J. W. Abbiss, C Bremer, C F Campbell, W M. B. Davidson, R. J. Dinsmore, R H. Maudsley, G. A McKaig, L. J. Page, G J Rees, D. L Scott, B. H. B. Upton, D. Raeside, J Abrahams, S. S. Hart, R. V. Imrigh, S Lindsay, C. Rutter, and J. K. Wright.

Dr. Arthur Carr, registered as of Brick Lane, London, E.1, has been granted leave by a King's Bench Divisional Court to serve notice upon the G.M.C. of a motion for an order of certiorari to quash its order erasing his name from the *Medical Register* (*Supplement*, Dec. 12, 1942, p. 73).

ASSOCIATION NOTICES

Psychological Medicine Group Committee

The following have been elected members of the Psychological Medicine Group Committee of the B.M.A. for the three years 1943–6: Dr. N. H. M. Burke (St. Albans), Prof. Millais Culpin (London, W.1), Dr. R. Eager (Exeter), Mr. T. Lindsay (Caterham), Dr. J. H. MacDonald (Luss), Dr. W. G. Masefield (Brentwood), Dr. Doris M. Odlum (London, W.1), Lieut.-Col. A. A. W. Petrie (Sutton), and Dr. R. M. Stewart (Leavesden).

Diary of Central Meetings

MARCH

31 Wed. Joint Conference of Members of the Special Representative Meeting and of Members of the Special Conference of Representatives of Local Medical and Panel Committees, 9 30 a.m.

Special Representative Meeting, 1.45 p.m. approximately.

Special Conference of Representatives of Local Medical and Panel Committees, 3 15 p.m.

Branch and Division Meetings to be Held

BIRKENHEAD AND WIRRAL DIVISION.—At Arrowe Park Hotel, Woodchurch, Birkenhead, Sun., March 21, 5.15 p.m. Agenda: Consideration of the motion on the Beveridge report published in the *Supplement* of Feb 13, and instruction of Representatives to Special Representative Meeting on March 31, etc. 6 p.m. General meeting open to all practitioners in the area of the Division.

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thurs., March 25, 2 15 p.m. Clinical demonstrations in the Out-patient Department. Address by Prof. J. C. Spence. Children in Medical Practice. All members of H.M. Forces serving in the area of the Branch are invited to attend

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m. Medical Clinics, Surgical Clinics and Operations. Obstetric and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m., Post-mortems *Mon.*, 2 p.m., Ear, Nose, and Throat Clinic *Tues.*, 10 a.m., Paediatric Clinic; 11 a.m., Gynaecological Clinic; 2 p.m., Genito-urinary Clinic. *Wed.*, 11.30 a.m., Medical Conference. *Thurs.*, 3 p.m., Dermatological Clinic. *Fri.*, 12.15 p.m., Surgical Conference; 2 p.m., Gynaecological Conference; 2 p.m., Sterility Clinic.

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W.—*West End Hospital for Nervous Diseases:* Tues and Fri., 3 p.m., M.R.C.P. course in neurology *London Homoeopathic Hospital:* Wed afternoon F.R.C.S clinical demonstration (Limited to 6.) *Royal National Orthopaedic Hospital:* Sat. afternoon F.R.C.S orthopaedic course. (Limited to 6) *Radcliffe Infirmary:* Daily, Revision course in anaesthetics *St. Mary Islington Hospital:* Wed., 2 p.m., F.R.C.S clinical course. *National Hospital for Diseases of the Heart:* Tues and Wed., 10 a.m., Out-patient clinics.

DIARY OF SOCIETIES & LECTURES

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—*Tues.* and *Thurs.*, 2.15 p.m. Oliver-Sharpey Lectures by Prof. G W. Pickering: The Circulation in Arterial Hypertension.

Serving Doctors and Medical Reorganization

SIR,—Many letters to you have given the disquiet that there is among many of us that the younger practitioners, now in the Forces, have not contributed to the discussions upon the future of medical practice and medical work. May I make a practical suggestion?

In our area we have done our best to get the very many serving doctors to attend the various meetings, not only of the study groups but also the more general discussions. Not one has attended. Let us, therefore, now go after them in their Service haunts. For instance, I am suggesting to our local honorary secretary that one or two of us offer to attend one night or two at two very large local camps, one of which has no fewer than eleven doctors and nine dentists on its staff, and that we take with us to guide the discussion the findings of our local study group. In this way serving doctors would hear what those in practice are thinking, and could give their opinions and voice their feelings. The results could then be sent to headquarters for use in producing any final proposals.—I am, etc.,

A. T. SCHOFIELD.

SIR,—I ask the hospitality of your hard-worked columns to voice an opinion which is probably widely held among those G.P.s who are tied to Service duties while all these great deliberations regarding the future of the profession of general medical practice are taking place.

In peacetime I had the privilege of serving as a member of the Middlesex Panel Committee as well as on various committees of the B.M.A. After a few months of war most of these committees suspended their work as fully representative committees, and appointed small—very small—executive subcommittees to carry on routine work under wartime conditions. An offer to resign and make way for another doctor, still in general practice, on these committees was politely rejected on the grounds that such committees could not be fully representative in wartime and proper democratic *elections* would take place after the war to reconstitute such committees with full mandate to represent the interests of the G.P.s concerned.

Now the future status and livelihood of the profession are under discussion, and indeed negotiation with the Government for radical alteration. The Government have cleverly agreed to proceed, after agreement in negotiation with the profession, with implementation of the postulates of the Beveridge report, but no mention is made as to how the opinions and views of the most vital, youthful, and therefore most important section of the profession, who are in the Forces, are to be obtained or given consideration.

I therefore appeal through your columns to those senior colleagues who are at present in power so far as the medico-political organization is concerned to remember that nothing they agree to can be accepted as binding on those of us who are unable to state our views democratically, unless a referendum to the whole profession is taken and negotiations based upon the majority view resulting therefrom. It should be made clear to the Government that the future medical services of the nation are dependent upon the work that doctors at present in uniform are prepared to undertake with confidence and enthusiasm when they are returned to peaceful pursuits. The opinions expressed by various committees at the present time are not in any way representative of the views of this large but necessarily silent number.

The urgency of coming to decisions regarding the proposed establishment of fuller national medical services on the recommendation of Sir William Beveridge is obvious to us all, but, at the risk of tedious repetition, I would again emphasize that a referendum to the whole profession is absolutely essential, and reliance upon existing medico-political organization most unwise and undemocratic, for the reasons outlined above.—I am, etc.,

ALISTAIR FRENCH,
Wing Commander, R.A.F.M.S.
Hon. Treasurer (in absentia), Metropolitan Counties Branch, B.M.A.

At a Division Meeting

SIR,—I hope that every member of the B.M.A. will attend his local meeting whenever anything in connexion with State medicine and the Beveridge plan is under discussion. Unfortunately, the more successful practitioners, who are therefore the busiest, have not usually the time to attend these meetings, and, as a result, decisions are taken which affect their whole future and which they declare too late they know nothing about.

I attended the local B.M.A. meeting at Guildford which was to instruct our delegates how to vote at a Representative Meeting on March 31. It was decided that it was not necessary to discuss Clause (*a*), for which I was sorry as I do not think there are enough doctors in the country to supply a comprehensive medical service. It must be realized that under such a scheme patients will bring all their minor ailments to the doctor, which they have previously treated themselves or taken to the chemist. As a result it may be difficult to separate the wheat from the chaff. In other words, serious cases may be overlooked. I consider that at least three times as many doctors will be necessary as are at present available. This, however, was already agreed upon, and we discussed an amendment of Clause (*b*), proposed and seconded by members who were actually to be delegates to the conference. They proposed to delete Clause (*b*) altogether, and they put their case with the deepest sincerity. They were obviously idealists, and, although I have realized that the trend of the nation is definitely communistic, if that is what is meant by the subservience of the individual to the State, their speeches were a shock to me. The outstanding phrase in their speeches was "whether we like it or not," and I felt that I must belong to a profession which had failed in its service to the public instead of to a profession which had always put the interests of the patients first and its own last. I had thought that our delegates would be more concerned in safeguarding the interests of the doctors, but apparently their chief thought was the safeguarding of the patients against the doctors. I am pleased to say that the proposal that the amendment to Clause (*b*) should be deleted was rejected, and yet these delegates will go to the conference on March 31 to vote in favour of Clause (*b*), of which they do not approve. This seems wrong to me.

I suggested—and I admit that my suggestion was thought by the meeting to be unnecessary—that it would be well to have some idea of what we are to be paid as State doctors before deleting Clause (*b*). Personally, if I am to be paid an adequate salary, I have no desire to do private practice. If, however, the doctors are to be paid £800 or less, then many doctors will be unable to meet their commitments, which they entered into quite justifiably in view of their income and their expectation to earn such an income for some years to come, and they must demand the right to augment it in this case. I mentioned £800, as I believe this is the sum which was arranged as a whole-time salary for the most specialized members of the profession for their services under the E.M.S. scheme, and they were debarred from private practice. When the E.M.S. came into operation at the beginning of the war these doctors protested that their salary hardly paid their Harley Street rents, to which they were committed by leases. They had shown the same apathy while these arrangements were being made which members of the profession are showing now while idealists may negotiate their economic downfall.

We were told that we were to be compensated by a capital sum for our practices just as in the case of coal-owners and their mines, but I am sure that their negotiators would not be quite so altruistic as ours. I feel that this time of war, when all our sense of values is distorted by the horrors and the sacrifices of our fellow-men, is not the time to negotiate a final decision for all time, from which there will be no drawing back, on the whole future of medicine. The trend at the moment is communistic or "all for the State," just whatever label one prefers, but our history has shown that the higher the pendulum swings in one direction it usually swings later an equal distance in the opposite direction. In a few years' time it may be found that, while the rest of the nation who are still free have gone all individualistic, the doctors are for ever imprisoned in a net of State bureaucracy.

Let us wait for State medicine until this war is won and all the registered medical practitioners, whether they are members of the B.M.A. or not, can vote on this subject which decides their future. The banking interests and the powerful approved societies will keep the theories put forward by this Oxford professor in their proper perspective, and it is up to the doctors not to be blinded by sentiment in times which are necessarily hysterical when their own interests are at stake.—I am, etc.,

Camberley. LESLIE HARTLEY.

Does the Public Know?

SIR,—The spate of correspondence and special articles in regard to the medical profession and the Beveridge report has made the *Journal* unusually interesting and entertaining reading. When all is said and done, however, surely most of it is waste of effort, since the *Journal* is a closed book to the general public. If any good is to come of these expressions of opinion, excellent argument, and such a clear and precise statement of our case, surely means should be found to bring them to the notice of the public, who are sublimely ignorant of our point of view.

It is common knowledge among the practising profession that our patients have no conception of the conditions under which we are called upon to carry out the services of National Health Insurance. As has been pointed out more than once in your columns, it has been found that on the occasions when the cheese-paring and totally inadequate nature of the capitation fee has been brought to the notice of insured patients they express surprise and amazement, having been under the impression that we were adequately remunerated for our services. Had the general public known the facts of the recent negotiations with the Minister upon this matter of the capitation fee we should undoubtedly have had the sympathy and support of the public for the justice of our claims, a matter of no mean political importance.

The same would seem to be of paramount importance in regard to the negotiations now in progress concerning the implications of the Beveridge report and the status of the profession whose duty it will be to carry out the health services envisaged in that report. We must see to it that the public are made familiar with the issues at stake from our point of view as well as from their own. Letters and articles in the *Journal*, excellent as they are, are of no value so long as they remain within the secretive covers of the *Journal*. These, no doubt, give great satisfaction to those of us who have not the time or the gift of expressing ourselves, but beyond that serve no useful purpose whatever. The public must be made aware of the facts if there is to be any hope of a satisfactory health service or a fair deal.—I am, etc.,

Oxford. J. FRANKLAND WEST.

Representation of the Profession

SIR,—Is it not a fact that the views of the Representative Body in no way represent the feelings of the whole of the medical profession? Many practitioners do not belong to the B.M.A., and those who do find it difficult to attend Division meetings owing to pressure of work. Could not a questionary on controversial matters be sent to all practitioners normally resident in the British Isles? If this were done I feel you would obtain little confirmation of statements such as the following in your leading article (Feb. 13, p. 193): (1) "The idea of a complete service on a compulsory insurance basis is already accepted by the medical profession for roughly nine-tenths of the population." (2) "The 100% proposal does not necessarily imply a whole-time State salaried service." Perhaps not, but it is the thin end of the wedge, and against the wishes of a 49% minority at the last Annual Representative Meeting.

Let us, therefore, be democratic, respect minorities, have our questionary, and find out what really is the feeling of the profession.—I am, etc.,

Leominster. GEOFFREY M. HOUSDEN.

RECRUITMENT OF PUBLIC HEALTH MEDICAL OFFICERS

The Ministry of Health states that notwithstanding the notice contained in Circular 2440 some local authorities still try to fill vacancies on their medical establishments without first consulting the Central Medical War Committee. It cannot be too strongly emphasized that the deferment granted to a medical officer in the employment of a local authority relates specifically to the post then held by him, and if he leaves that post and applies for another under a local authority he immediately renders himself liable to recruitment. In his own interests he should, before entering into any commitment, ascertain from the Central Medical War Committee what his position would be if he accepted a specified new appointment. It will be open to the two local authorities concerned in any change of employment to make representations to the Central Medical War Committee against recruitment. The Ministry of Health would consider whether on the merits of the case it was justified in supporting such representations. Such support would not normally be forthcoming if there were other suitable candidates not liable to military service, or if it were considered that by staff adjustments or by co-operation with another authority the work could be carried on without making an appointment.

H.M. Forces Appointments

Why Reorganize?

SIR,—The more one studies the Beveridge plan in its relationship to a comprehensive medical service the more one is at a loss to understand the reasons for its inception. If its sponsor, *or sponsors*, pretend that the scheme is necessary so that all branches of medicine are available to the poor and sick alike, they either show profound ignorance of the true facts or have based their premisses on untruth.

Having been in general practice—mixed panel and private—for 30 years I state emphatically that my poorest patient can obtain any medical service free that can only be obtained by the richer patient on payment of fees. This includes examination by consultants, surgical operations if required any laboratory tests of specimens, *x*-ray examination, etc. Whenever I have sent one of my poorer patients for complete investigation to the infirmary—and I use three different ones—I have always received every help and courtesy from the "honoraries" and other medical officers, and so indeed has the patient. So far as I know, in 25 years there has not been a complaint here by any patient to the insurance committee that *any* service was not available because they could not pay for it.

As I regard myself as an average G.P., with a good number of poor people to look after, I am certain that my experience is that of thousands of my colleagues. Therefore, I state that this attempt to revolutionize the medical profession has not come from within its own ranks, and thousands of us want to know how and where it began. What can a layman like Sir William Beveridge know of the purely technical side of our profession? What would happen if the President of the B.M.A. formulated a scheme for the reorganization of the legal profession, and tried to foist it upon an apathetic public? Would this go unchallenged? If I suggest that this attempt to tear up the roots of and to regiment this scientific profession of ours was conceived by one or more of the great co-operative societies are there many who will disagree with me? The danger signal is there for us to see; I regard it as the twilight of the G.P.—the family doctor—and the squashing of all that is good in the profession. When the Minister of Health, buttressed by the permanent Civil Service officials in Whitehall, and the representatives of the medical profession meet to discuss how far into the social whirlpool doctors are prepared to be sucked, one can only hope that those thousands of younger medical men and women serving in H.M. Forces will not be forgotten. They have no voice, and if they are to be faced on their homecoming with the fact that they are to be "robotized," that individual enterprise and hard work are to receive the same reward, financially, as the slacker, then will they know that democracy and all it entails was just another political shibboleth. We practitioners in the twilight of our working days have no axe to grind, but may I conclude by beseeching the B.M.A. to use all its powers in what will be its final fight to preserve all that is essential to maintain the integrity of the profession it represents, and not permit it to be the prey of any autocratic or monopolistic junta—political or financial.—I am, etc.,

JAMES LEACH.

State Medical Service

SIR,—As a former member of a State service—namely, the West African Medical Staff, which, fortunately, in my days had the privilege of private practice—might I ask the advocates of a complete State service (with medical officers upon a salary basis) the following question.

A. Who, in their proposed State service, is to decide where a practitioner is to be posted? For example, if a medical officer wishes to be posted to Torquay, who is to decide whether he goes there or to a vacancy, say, in Peterhead, Limehouse, or Wigan?

B. In such a service members would almost certainly be subject to the usual bureaucratic discipline. In the event of a conflict of opinion between medical officers will any of them be subject to the disciplinary punishment of being transferred elsewhere against their will? This is one of the favourite "remedies" of bureaucratic chiefs in order to discipline subordinates whom they consider "troublesome." This often means that the officers in question are keen on their work and progressive, and, as a consequence, are naturally rather disturbing to their chiefs.

C. What limit is to be put upon the number of patients each practitioner is called upon to attend?

D. Why should a medical officer in a salaried State Medical Service work any longer hours than a member of the ordinary Civil Service, which is usually less than 8 hours a day? As a corollary, why shouldn't the Government provide for three shifts of duty of 8 hours each 24 hours and pay for them? Naturally, this would call for a large increase in the numbers of the medical profession, and the Government would have to plan how to obtain it. Such an arrangement would, however, abolish the conditions of sweated labour which exist in the medical profession.—I am, etc.,

Highgate, N.6. E. E. MAPLES.

Treatment *En Masse*

SIR,—The criticism of the B.M.A., which must, I think, be uppermost in the minds of all thinking and experienced practitioners, is this: It accepts the medical aspect of an implication which runs through practically all recent legislation not only in this country but in all others which profess "Western civilization." That implication is that 90% of people consist not of individuals but of crowds, and must accordingly be dealt with *en masse*. From the medical standpoint this involves also the assumption that in illness there is not a patient to be treated in the first place but merely parts or aspects of a patient. The Beveridge medical scheme will not see the patient in his own home—that is, in his own domestic circumstances—nor will it look on him as a person with a history, since the sufferer will only consult the doctor casually and at intervals; moreover, he is as likely as not to see different doctors at different times, and will thus often get different advice from each. For thorough diagnosis and therefore thorough treatment an understanding of the patient's continuity both in space and time is essential. But opportunity for this understanding will be denied in future to the large majority of doctors. I shall not elaborate just now what I believe will be the inevitable psychological result of this on our practitioners, but I know that the treatment they give the patients will be, in 90% of cases, superficial at best. And the *vis medicatrix naturae* cannot be expected to help them out of all holes!

It is crystal clear now that Western civilization is rapidly sinking into decrepitude. But why should we assume that the Hippocratic, of all arts, can do no better than follow it step by step?—I am, etc.,

North Queensferry, Fife A. J. BROCK.

Study Groups

SIR,—I think it would be of great interest to other study groups to record our experience of a most cordial meeting with our M.P., Sir John Jarvis. We asked him to attend one of our discussions, first as a listener with a view to letting him know just what we were thinking, and later reciprocally learning from him how the House handles problems such as the proposed State Medical Service.

Our Member told us that he much appreciated this personal contact with his medical constituents, and expressed the view that all M.P.s should be invited by their local study groups to such meetings. We on our part realized that it would be no use submitting 50-50 voting as suggestions to Parliament, but that as a profession we must achieve something like unanimity in our views; and also that we were a very small drop in the bucket of post-war problems and expenditure, and must comprehend where we stood in relation to the whole.

My object in writing this letter is to endorse to the full our Member's suggestion, and recommend it most strongly to all study groups as likely to produce an extremely interesting and informative meeting.—I am, etc.,

G. H. STEELE, M.S., F.R.C.S.,
Secretary, Guildford Study Group.

First Things First

Sir,—The majority of doctors must have been very worried for some time past by the revolutionary changes which are proposed for their profession, and I am sure that, like myself, they must have felt a new ray of hope when they listened to Mr. Churchill's broadcast speech on March 21. He said, "Don't take your eye off the ball for a moment." What is our ball? Surely, it must be the care of our fighting men by those doctors in the fighting Forces, and the care of the workers at home by the civilian doctors. These two essential tasks are already straining the medical profession to the utmost limits, and when there is a second front they will be strained even further. I think, therefore, that this comprehensive medical service should wait until Mr. Churchill's Four Years' Plan after victory has been won.

At the end of his speech Mr. Churchill exhorted us to "act with comradeship and loyalty to our country and to one another" and "to make State enterprise and free enterprise both serve national interests and pull the National wagon side by side." After that, I think, there is no further need to discuss Assumption B.—I am, etc.,

Camberley. Leslie Hartley.

Correction

Mr. H. J. McCurrich (Hove) writes that the word "principle" in the eleventh line from the end of his letter (March 20, p. 37) should read "principles," as it refers to the three principles in paras. 7, 8, and 9 of the Beveridge report.

---

The Scottish Medical Advisory Committee, the appointment of which was announced by the Secretary of State for Scotland recently, held its first meeting and discussed chiefly the Government's acceptance of Assumption B of the Beveridge report. It recommended that negotiations between the Department and the medical profession should start with consultations with the Scottish Branch of the B.M.A., and this Mr. Tom Johnston agreed to do. Other matters discussed were the increased incidence of tuberculosis and venereal diseases. The committee has been appointed in the first instance for three years.

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue

BIRTHS

Bain.—On March 26, 1943, at 120, Woodcote Road, Caversham, Reading, to Kathleen (*née* Falla), wife of Lieut W Ivor Bain, R.A M C (B.N A F), a sister (Sheena) for Alistair.

Wilkie.—At the London Hospital on March 3, 1943, to Mary (*née* Duffy, S.R N), wife of Captain D R P. Wilkie, R A.M C., a son.

Members of the B.M.A., and especially members of the Council and of a number of central committees, will learn with pleasure of the presentation made to Dr. Ernest Ward on his retirement from the post of Tuberculosis Officer for South Devon. At a meeting of the Torquay Division on Feb. 28 Dr. Ward was handed a cheque to which more than 90 of his colleagues had subscribed. In making the presentation the chairman of the Torquay Division, Dr. Morton Palmer, said that Dr. Ward had fulfilled the promise of his youth as a distinguished scholar of Cambridge University, by his work as a surgeon and a tuberculosis specialist, by his contributions to literature, and as an acknowledged authority on birds His most noteworthy attainments, however, were in the medico-political field, and the Torquay Division had been fortunate in having Dr. Ward to represent it for the last 30 years.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY APRIL 10 1943

"DISCUSSIONS WITHOUT COMMITMENT"

CONSULTATION BETWEEN GOVERNMENT AND PROFESSION

JOINT MEETING OF REPRESENTATIVE BODY AND PANEL CONFERENCE

A Joint Conference of members of the Representative Body and of the Conference of Representatives of Local Medical and Panel Committees was held in the Great Hall of B.M.A. House, London, on Wednesday, March 31. Its purpose was to consider the Government's invitation to enter into discussions with regard to Assumption B of the Beveridge report. Dr. H. GUY DAIN of Birmingham was in the chair, supported by the President of the Association, Sir Beckwith Whitehouse, the Chairman of the Council, Mr. H. S. Souttar, the Chairman of the Representative Body, Dr. Peter Macdonald, and the Treasurer, Dr. J. W. Bone. Almost every B.M.A. constituency and insurance area in Great Britain and Northern Ireland was represented. The Joint Conference, which occupied the whole morning, was followed by a special meeting of the Representative Body in the early afternoon, and this in turn by a Special Panel Conference, at both of which meetings the main recommendation agreed to at the Joint Conference was brought forward and accepted. At the outset of the proceedings a telegram of good wishes was read from the Polish medical section in London.

The Governing Resolution

The first business of the Joint Conference was to receive a statement by the Chairman of the Council, after which the following resolution was proposed and debated:

> That it be recommended to the Representative Body and to the Joint Conference of Local Medical and Panel Committees:
>
> (1) That the Government's invitation to enter into discussions without commitment be accepted.
>
> (2) That a committee representative of the profession as a whole should, in response to the Government's invitation, now enter into discussions with representatives of the Minister of Health on "a scheme for comprehensive health and rehabilitation services, for the prevention and cure of disease and restoration of capacity for work, available to all members of the community" (Assumption B of the Beveridge report), in the light of the following undertakings now given:
>
> (*a*) That, at the conclusion of the discussions and at the appropriate times during the discussions, but in any case before negotiations open and before any proposals are submitted by the Government to Parliament, the full machinery of the Association, including the Council and its Committees, Groups, Panel Committees, Divisions, and the Representative Body, will be used to consider the Government's proposals and to decide the Association's view thereon.
>
> (*b*) That every practicable step will be taken to give all members of the profession, whether members or non-members of the Association, an opportunity to express their views and in particular that every practicable step will be taken to give to members of the profession on Service an opportunity of expressing their views, to assess those views, and to present them to the meeting or meetings of the Representative Body called to consider any proposals by the Government.
>
> (3) That the composition of the Representative Committee, as reported in the statement published in the *Journal* of March 20, with the additions announced at this meeting, be approved.

Clause (1) of the above recommendation was carried with only two dissentients; clause (2) was carried without dissent; and clause (3) was carried by a large majority. To complete the personnel of the Representative Committee it was announced that Dr. J. H. Sheldon of Wolverhampton and Mr. H. J. McCurrich of Brighton had been added to represent staffs of provincial non-teaching hospitals, and Dr. E. R. Williams of South-West Wales to represent rural practitioners. The request of the Society of Apothecaries to nominate a representative in general practice had been accepted, and nominations were awaited from Northern Ireland, whose Government proposed to move *pari passu* with the British Government in this matter. A motion to include representatives of the Medical Practitioners Union was lost.

At the Special Representative Meeting the recommendation was brought forward by Dr. Dain, seconded by Dr. J. B. Miller, and clause (1) was agreed to without dissent, and clauses (2) and (3) were agreed to with very few dissentients. At the Special Panel Conference clauses (1) and (2) were agreed to almost unanimously. To clause (3) an amendment was carried recommending that it be remitted to Scotland to elect its own representatives other than those already nominated by the Royal Scottish Corporations. With this amendment clause (3) was agreed to.

Below is a summarized report of the proceedings of the Joint Conference. The proceedings of the Special Representative Meeting and of the Panel Conference will be reported in a later issue.

PROCEEDINGS OF JOINT CONFERENCE

Statement by Chairman of Council

The first business of the Joint Conference was to receive the announcement published in the *British Medical Journal* of March 20, p. 359, on consultation between the Government and the medical profession.

The CHAIRMAN OF THE COUNCIL (Mr. H. S. Souttar), who was heartily greeted, said that, whatever views they might hold about the future of the profession, this was one of the most important meetings ever called by the British Medical Association. The Association represented not one or other group, not general practitioners or consultants as such, but the profession as a whole. Before the war the Association had formulated its policy for a comprehensive co-ordinated service based on the two-way extension of the National Health Insurance service. With the coming of the war it became evident that in the period which followed the cessation of hostilities there would be great changes in the whole basis of their work; therefore the Medical Planning Commission was set up, and published its interim report last summer. In November, when the Beveridge report appeared, it was seen that some of the ideas expressed by the Commission had been adopted in that document, though details were not considered.

The Council regarded the Beveridge report of such importance as to call for reports on its proposals from certain of the standing committees and the group committees of the Association and for the eventual summoning of a Special Representative Meeting. At every stage the Council had done all in its power to take the Association into its confidence. (Some cries of "No.") After the Council meeting at which it was determined to summon the Representative Body a new situation developed in the shape of an invitation from the Minister to the Association to arrange for a body representative of the whole profession to meet him and discuss the Beveridge proposals. If the invitation had been for a representative body of the Association it would have been easy, but the Association was asked to arrange with other bodies which also claimed a right to speak for sections of the profession. The committee, the names of whose members appeared in the *Journal* of March 20, was accordingly set up. It had been complained that the Divisions should have been asked to elect representatives on this committee. There was no time for that. The request was made on February 18, and they were called upon to meet the Minister on March 9. ("Why?") Because at that very time a meeting between the Minister and representatives of local authorities and of the hospitals had already been arranged. If the Association had postponed the meeting, so that the Minister had entered into discussion only with the local authorities and others outside the profession, would not criticism have been made, and rightly of Association lethargy and timidity?

These recent developments had altered the situation. In the motion previously framed, which it was intended to lay before the Representative Body, it was proposed that if Parliament adopted a certain position with regard to the Beveridge proposals the Association, on certain conditions, would be willing to co-operate. The Government had since decided to adopt a large number of the proposals, and it was now imperative that the profession should accept the invitation to enter into consultation with the Minister as to how one of those proposals was to be implemented. For this purpose there must be a committee, but he stressed that the committee was only a discussions committee, not a negotiating committee. Its members would return to the bodies they represented to obtain their views on whatever proposals might be put forward. He moved: "That the Government's invitation to enter into discussions without commitment be accepted."

A Complaint of "Sidetracking"

Dr. G. DE SWIET (London) said that the Government had not accepted the Beveridge report. In the debate in Parliament the Minister of Health was not even one of the Government speakers. Following that debate there was a wave of disappointment, and then the Minister performed an act of appeasement with his proposal for a National Health Service scheme; while the Beveridge report "taken as a whole" (the vital words in the resolution by the Council which apparently was not now to be taken) was shelved. Yet a meeting had taken place on March 9 between the Minister and this self-appointed body. The further the new scheme was allowed to drift away from the Beveridge report the less would it prove to be anything really new. It looked as though Beveridge was merely a decoy. At this rate there would certainly be no complete structure of social security under a special Ministry, and perhaps even the Friendly Societies would manage somehow to survive.

Mr. MCADAM ECCLES reminded the meeting of the crisis 34 years ago at the advent of National Health Insurance. There was some danger that history might repeat itself. It was thought in those early days that the profession had a cohesion which would enable it to go forward for the benefit of the people as well as for that of the profession itself, but when legislation came the cohesion proved to be only on the surface. He made a strong appeal for a statesmanlike discussion of fundamentals. If in that way agreement were reached they could carry the whole profession and even Parliament with them.

The Question of Leadership

Sir KAYE LE FLEMING, as one who had taken no part whatever in these proceedings, said that when he read the announcement that the Minister of Health had asked the Association to compose a body of men representative of the whole profession his only sensation was one of pleasure that the importance of the Association had been so recognized. (Applause.) Had he still been Chairman of the Council his action would have been the same as the present Chairman had taken. Some appeared to think that this matter might have been delayed. He disagreed most emphatically. If the Executive or Council had said that it was not prepared to meet the Minister with a committee of this kind until the matter had been referred to the whole country, the Minister would have asked the Royal Colleges and some other bodies to do what he wanted. The occasion was urgent, and the action taken was in the best interests of the profession.

Dr. D. L. S. JOHNSTON (Halifax) could not believe that there was need for such haste in appointing the committee. Its appointment might have been delayed until after the present conference. It was suggested that, if there had been delay, the Minister would have gone to some other quarter. But could the Royal Colleges or the Society of Medical Officers of Health run the health services of the community? He begged members not to be intimidated by the suggestion that if they did not at once do something, something would be done for them. Last year the Panel Conference had to be postponed because the Minister was not ready. The profession had an equal right to ask him to wait until they were prepared to meet him.

Dr. HOWIE WOOD (Isle of Wight) said that their constituents did not expect that when major issues arose the Council of the Association or the Insurance Acts Committee should refer everything back to them. They were glad that their leaders acted as leaders. Before an irrevocable step in policy was taken they should certainly be consulted, but they should trust their leaders to do this preliminary work. The committee would collect information from the Government and report back to the constituting bodies before action was taken. It was not a negotiating body. If this leadership had not been forthcoming there would have been good ground for criticism.

Three members of the Council defended what had been done. Dr. P. INWALD asked how they could as responsible people have refused to discuss with the Minister the future of the service. The Government had a right, if it wished, to introduce a comprehensive service. It was the profession's job to see that the Government's proposals were on the right lines. Dr. W. W. FOX said that it was futile to declare that they must not negotiate with the Ministry. The Council or its Executive had acted democratically. It was right to appoint the committee; whether or not the right people were chosen was another matter. Major SCOTT STEVENSON said that he had come down from the Highlands to protest about the way in which the committee had been set up, but at the Council meeting on the previous day he had discovered that he was completely wrong, and he ate his words. There was urgency; it was an urgency which should never have arisen, but that was the fault of the Ministry, not of the Association.

The motion "That the Government's invitation to enter into discussions without commitment be accepted" was carried with only two dissentients in a meeting which must have numbered about 400.

Consultation with the Rank and File

Prof. R. M. F. PICKEN then moved Part (2) of the long resolution set out in the introduction to this report, empowering the committee to enter into discussions on a scheme for comprehensive health and rehabilitation services available to all members of the community (Assumption B of the Beveridge report) in the light of undertakings to use the full machinery of the Association to consider the Government's proposals and to take every practicable step to give all members of the profession an opportunity to express their views. He recalled the history of the Association's proposals for a General Medical Service for the Nation. The Medical Planning Commission had started with the knowledge that the profession had already accepted proposals of a very extensive nature, and its own revolutionary proposals were to a large extent accepted by the last Annual Representative Meeting. Thus the democratic machinery of the Association had been constantly used in building up the policy. The profession went into these discussions with the Government prepared in a way in which it had never been prepared before. He was sure that the Government was perfectly honest in saying that it wanted to get on quickly with the discussions in order that it might be prepared for whatever conditions would arise after the war. Even the Prime Minister, who had constantly said that the primary business was the winning of the war, had in his latest broadcast affirmed the need for laying the groundwork for these social matters even while the war had still to be won.

Dr. R. W. COCKSHUT (Hendon) said that democracy expressed the will of the majority and protected the rights of the minority. The representatives of the profession must represent the majority views. The profession had insisted, even with vehemence, that it was opposed to a whole-time State salaried service. That feeling had even gained ground during the last few weeks, and the profession was now united on this point as never before. His criticism of the Council was that it had not ensured that the members of this committee were in full accord with the views of the Representative Body. The committee included men who were known to be strong advocates of a State Medical Service. This was not democracy, it was anarchy. Unity through the British Medical Association was their only hope as a profession. He urged that the meeting should take its stand on certain principles: that the relationship of doctor and patient as at present constituted should not be impaired or disturbed; that freedom of choice should be preserved, and present restrictions on that freedom so far as possible removed; that in no sense should the doctor become either a civil servant or a Government official; and that the autonomy of the profession should be kept as inviolate as the autonomy of the profession of the law. Another point of insistence should be that no medical man should, as a result of changes which came about, suffer any loss of capital or income.

Dr. A. SMITH POOL (Glasgow) said that there was too much urgency about this question. He wanted to slow down the speed of radical reform in medical practice. Delay in reorganization was not going to deprive people of necessary medical attendance. Thousands of doctors in the Services had a right to be heard, perhaps a better right than most of those present that day, and if a bad bargain were made in their absence it would sow the seeds of future strife within the profession. These absent men should have a voice in the final settlement. It seemed to him that the Beveridge plan, if adopted, would split the medical profession into two parts—private practitioners and contract practitioners.

The Chairman (Dr. Dain) said that those concerned were well aware of the necessity for being careful and not rushing matters. The urgency was that the profession should be in at the beginning of these discussions; having got in, there was, as he saw it, no further urgency. No extension of services was possible, of course, while the war was on.

The Rural Practitioner

Dr. E. R. Williams (South-West Wales) wished to raise a question which concerned only a small minority of practitioners—namely, those in very sparsely populated areas. In West Wales his next medical neighbour in one direction was 23 miles away, and in another direction 15 miles. Was there on this committee a practitioner who was suitable to represent these very difficult practices? The Chairman said that at the meeting of the Council on the previous day it was felt that one of the gaps in the membership of this committee was the absence of a rural representative, and Dr. Williams's own name was suggested.

Dr. J. A. Ireland (Shrewsbury) said that this was not the time to revolutionize the whole practice of medicine. Whatever was decided as the result of this committee's so-called discussions or negotiations—and where the former became the latter no one could tell—would be fixed in perpetuity. There was one snag in the motion by Prof. Picken. It was in the words "available to all members of the community." At the last Annual Representative Meeting the proposal to have a comprehensive medical service covering 100% of the population was carried by 94 votes to 92, but he did not think that the vote represented the view of the meeting. It was rather put in the form of the question: "Should everybody have a decent standard of doctoring?" to which, of course, the usual answer was "Yes." He felt that the so-called urgency was political expediency and nothing else. It was "rubbish" to say that the position was comparable to 1910. Negotiations were then being carried on with a prospect of increased payment for work done—the insurance capitation fee as opposed to the old club rate—but to-day there seemed to be nothing except a State Medical Service or a 100% extension of the panel system.

Dr. R. W. Rae asked whether the Government demanded that there should be compulsory health centres in the new scheme. He did not see how these could be worked on a capitation basis.

Duty to the Community

Dr. J. R. Baker (Scunthorpe) said that they ought to be discussing not only what they got out of the community but what they gave to it. Sir William Beveridge had said that his scheme depended on a 100% contributory system for the whole nation. If an attempt were made to exclude health services from that contribution the Beveridge report would be torpedoed. To bring about such a result for the sake of the few private patients who were left to them was to do less than their duty to their absent colleagues. He would hate to see these men now in the Forces dragged back into a competitive scramble.

Dr. R. H. Mole, speaking as one of that "rare body," the under-thirties not in uniform, said that his Division (Oxford) had decided with a single dissentient that it would like to see every member of the community brought into the service. Only if the health scheme were fully comprehensive would a proper doctor–patient relationship obtain from the patient's point of view, while from the doctor's point of view it would do away with the difference in prestige between doctors who took private fees and those who took capitation fees.

Dr. A. M. McMaster desired to instruct the representative committee to insist on a fair settlement of the present capitation fee as an essential preliminary to any new discussions, but the Chairman said that this would cut right across the business of the moment, and he could not take such an amendment without notice.

Clause (2) of the resolution which had been moved by Prof. Picken was then, after a slight verbal alteration, carried in the form set out at the beginning. There were no dissentients.

The Composition of the Committee

The Chairman said that the next business was to approve or otherwise the composition of the representative committee as set out in the *Journal* of March 20 (p. 359). He added that no negotiations would be carried out by this committee, but discussions only; when it came to the stage of negotiations the personnel would have to be considered again.

The Chairman of the Council, in moving approval, said that the composition was determined after careful discussions with the other bodies, and personally he thought it a considerable achievement to have such a body brought together under the aegis of the Association. The bulk of its membership had been appointed on the most democratic principles. All the members had done sterling work for the profession.

In reply to Dr. Baldie, who asked whether the committee would have power to co-opt, the Chairman said that this had not been suggested, but it would have power to set up subcommittees to deal with specific points as they arose, and to these subcommittees outside persons, perhaps through the specialist group machinery of the Association, might be appointed.

Dr. D. L. S. Johnston (Halifax) protested against the committee on the ground that it had been very hurriedly appointed and was not wholly representative of the majority opinion of the last Annual Representative Meeting. There were members of the committee who were all out for a State Medical Service. This was not a question of personalities but of policies.

Claim of the Medical Practitioners Union

Dr. Gordon Ward (Sevenoaks) moved that two representatives of the Medical Practitioners Union be added to the committee. He said that the Union had between 5,000 and 6,000 members and had been in existence for 29 years. It published a weekly journal, and it did represent a genuine minority opinion. If it were excluded from these conferences with the Ministry three possibilities would be open to it. One would be to keep quiet and abrogate any further representation of its members; but that would not be an honourable course for any professional body. Another would be to join with some political party and work outside the profession to attain its end by political means. (He did not necessarily mean the Labour Party, for the Labour Party was bitterly opposed to the aims of the profession at the moment.) The third course would be, knowing nothing of what was happening, to continue urging its own policies in the Press or by memoranda, and then, surely, the enemies of the profession would play one section against the other. The Union wanted to join in a combined approach, and no sectional squabbles should prevent it. Dr. N. E. Waterfield asked whether the policy of the M.P.U. was a State Medical Service. Dr. Gordon Ward said that its policy was a State Medical Service, as was that of the Society of Medical Officers of Health, which was represented on the committee. But the M.P.U. would not be on the committee to represent the policy of State Medical Service any more than the B.M.A. would be there to represent the policy of non-State Medical Service.

Dr. E. A. Gregg said that he did not see any ground whatever for including this representation. He completely disbelieved the statement regarding the membership of the Union, of which no proof had been given.* The organization was not representative of the profession and would promote disunity within the body which had to deal with these serious matters. He had a vivid recollection of the extremely embarrassing position created at the Court of Inquiry on the capitation fee, and he was not yet satisfied that the intervention of the Union had not a great deal to do with bringing about the unfortunate result of that inquiry.

The motion to include representatives of the Medical Practitioners Union was defeated by a large majority.

The Position in Scotland

Dr. W. Jope (Lanarkshire) protested against the method adopted in choosing the Scottish representatives on the committee. The Insurance Acts Committee was given to understand that the committee as at first constituted would cease to function at the date of that conference, but since then they had had an announcement that the personnel, including six Scottish representatives, had been agreed. A combined meeting of the Scottish Committee and the Scottish Insurance Acts Subcommittee had unanimously protested against the method adopted. Scotland was not consulted with regard to the representation and was greatly dissatisfied.

Dr. Dain asked the Conference not to be carried away by the fervour of their Scottish friends. There were Scottish representatives on this committee, but Scotland had also a committee of its own to consider Scottish problems. It had also been a matter of complaint that the election had not been made from the constituencies. That was not the democratic method; electors in this country did not elect a Government, they elected a Parliament which itself chose or maintained in power a Government.

---

* At the Special Panel Conference Dr. Ward raised this question again and quoted figures, as also did Dr. Gregg in reply. A similar motion was rejected by that Conference.

Dr. J. A. MOODY (Stratford) believed that the small representation of the public health service and the lack of any accredited representative of industrial medicine were open to criticism. Dr. K. I. E. MACLEOD said that the medical members of any body which was to negotiate with the Government should have been elected by a vote of the whole profession. Dr. D. O. TWINING complimented those concerned on the selection, but pointed out the absence of any Service members. Dr. J. C. ARTHUR, speaking as a member of the Ministry of Health Advisory Committee, said that it could be accepted as certain that there was urgency, and to meet that urgency the Association had acted as democratically as possible in the circumstances.

Dr. J. F. LAMBIE replied to the Chairman's remark about a separate committee for Scotland; this was necessitated by the difference in Scottish services—for example, in relation to the Scottish Maternity Act and to the Highlands and Islands Scheme. But it was felt in Scotland that this committee appointed in London had not been set up as democratically as it should have been. A new committee had now been set up in Scotland for consultations with the Secretary of State and was on a democratic basis. In reply to a question he said that it was rather large, consisting of 52 members. Dr. I. D. GRANT asked for an assurance that a negotiating committee to replace the present discussions committee would not be nominated by the Council and come before the representatives as an accomplished fact. Dr. DAIN said that obviously the Chairman of that meeting could not give that guarantee; he could only say that before any negotiating committee was got together a Representative Meeting would be summoned.

The motion approving the composition of the committee was carried by a very large majority.

The Position of the Medical Advisory Committee

Dr. A. V. RUSSELL (Wolverhampton) raised the question of the Ministry of Health Medical Advisory Committee, suggesting that that committee be adjourned while the representative committee was pursuing its discussions with the Ministry. Many members were on both committees. Dr. J. A. IRELAND supported this view. It was impossible for a man to serve two masters.

Dr. A. T. ROGERS, a member of both committees, considered that there was some advantage in the interlocking. He added that the Advisory Committee was by no means a body of "yes men." After one session in which criticisms were put forward the Minister was doubtful whether he had an Advisory Committee at all. Prof. PICKEN, also a member of both committees, thought that the judgment of those who were in that position might be trusted. Dr. A. BEAUCHAMP thought that the fears underlying the suggestion of Dr. Russell were unfounded. The Advisory Committee was not there to agree with the Minister and did not hesitate to pronounce disagreement when it thought this was required. Without the Advisory Committee the Minister would be advised only by his own permanent officials. Dr. S. WAND spoke in the same sense. Their representatives on the Advisory Committee could be trusted; they were not "yes men," and they did represent a good cross-section of the profession. At the same time, he did not think it advisable that they should have referred to them matters which were under consideration by the new representative committee. Dr. J. A. BROWN, another member of both committees, hoped this matter would not be pressed. If the Advisory Committee ceased to function it would be quite easy for the Minister to get together another body, perhaps a body of "yes men."

Sir KAYE LE FLEMING saw no reason why the Advisory Committee, with the men they had appointed to it, should in any way jeopardize the discussions with the other body, and he could see very good reasons why it might be an advantage to have members of the Advisory Committee on the other committee.

After further discussion it was agreed, on the suggestion of the SECRETARY (Dr. G. C. Anderson), as an expression of opinion that during the present discussions with the Ministry no matters concerning Assumption B of the Beveridge report should be considered by the Advisory Committee. Dr. Anderson said that there were many matters on which the Minister desired the advice of the committee. The Advisory Committee had met on two occasions only; on the first it had considered certain questions arising out of the Venereal Diseases Regulations, and on the second, questions concerning mass radiography. The Medical Planning Commission had advised the setting up of an Advisory Committee to the Minister, and there was certainly room for one, but its work should not entrench on the representative committee which was now set up. Dr. RUSSELL, who had raised the point, expressed himself satisfied.

This concluded the business of the Joint Conference.

FUTURE OF MATERNITY AND CHILD WELFARE SERVICES

Representatives of some thirty different societies discussed the future of the maternity and child welfare services at a conference held under the auspices of the National Association of Maternity and Child Welfare Services. Varied views were expressed, but there was unanimity on two things: (1) the need for teaching parentcraft; and (2) the importance of a revised and improved training for the medical student and doctor. One or two speakers saw the family doctor of the future as teacher and guide of those under his care, an enthusiast for positive health, anxious to be responsible for ante-natal and child supervision, but preferring to be a diagnostician rather than occupy himself with the treatment of acute disease, which he would apparently be prepared to hand over to specialists. Some members thought the consulting paediatrician and obstetrician should direct their respective services. Others suggested that if there was group medical practice at health centres it would be easy to arrange for some of the doctors to have special training and experience in child health; these might carry on the work of the present clinics in close contact with the health visitors, at the same time extending the child welfare services to embrace the curative as well as the preventive work; a consulting paediatrician would be available if necessary. It was agreed that the present break in the child welfare services at the age of 5 was an artificial one, and that the school medical service should be part of the general arrangements for child health. Other points raised were the desirability of a new central Government Department to link up health and allied services, and the need for a new outlook on hospital ante-natal supervision, one which did not regard a row of healthy, energetic, young expectant mothers as "patients." It was suggested that in the meantime the National Association would do well to decide what parts of its work should be safeguarded in the future health service.

POSTURAL AND REMEDIAL EXERCISES

A display of postural and remedial exercises, arranged by the Inspector of Physical Fitness, R.A.F., with the kind permission of the Air Council, was given recently in London under the auspices of the Board of Registration of Medical Auxiliaries, Mr. V. ZACHARY COPE, President of the Board, being in the chair. Air Commodore A. C. CRITCHLEY, who opened the display, said that in his group they looked after the initial training of new recruits to the Air Force, who in the early stages needed very little remedial exercise. Later on, through the wounds of the war, remedial exercises were of great importance. The younger generation had not been told the importance of keeping fit. Those who cared for the initial training of the air crews of the R.A.F. saw the results of civil education, and there was a good deal which could be done which had not been done in the past but which, he hoped, would be attended to in the future.

A display of postural and remedial exercises was then given by two groups of R.A.F. recruits from an Air Crews Reception Centre. Wing Commander W. S. DAILEY said that a few days before these men had been civilians; they had not been chosen for their physique or for their fitness and ability, but were representative of the normal recruit sent in under their normal instructors. One group worked on foot defects and the other on spinal defects. The training was to encourage agility, standing, stretching, correct breathing, and so on.

At the end of the display Mr. Zachary Cope spoke on the scope and organization of the Board of Registration of Medical Auxiliaries. He said that medical auxiliaries were the skilled technicians in the various branches of the medical armoury. First there were the physiotherapists, represented by the Chartered Society of Massage and Medical Gymnastics, who not only carried out what the name suggested but also all forms of electrotherapy. Then there were radiographers, chiropodists, speech therapists, dispensing opticians, and orthoptists. The Board of Registration saw that those on its register were competent in their particular branch of medical science, and insisted upon the following criteria: (1) members must be well trained; (2) they must have passed a satisfactory examination; (3) they must keep a high ethical professional standard; and (4) they should in most cases work in co-operation with or under the supervision of a medical man. For the protection of the public it was necessary that there should be some way in which in any profession competent persons could be distinguished from the incompetent. For this purpose Parliament had from time to time passed Acts which laid down certain necessary qualifications that should be attained before the individual's name could be put on a register of those qualified to practise. The *Medical Register* was started in 1858, the Register for Pharmacists in 1868, and that for dentists in 1878. The midwives were legally registered in 1902, and the last to be registered by the State were nurses, whose register began in 1919. Until recently medical auxiliaries were the only group not listed in an independent register. But seven years ago Dr. C. B. Heald, now consultant in physical medicine to the Air Force, suggested to the B.M.A. that a register of medical auxiliaries should be formed, and thanks to the organizing ability of Dr. G. C. Anderson and the co-operation of Group Captain Cooper, backed by the B.M.A. and the Society of Apothecaries, a register was started and the Board of Registration of Medical Auxiliaries came into being.

At the conclusion of Mr. Cope's address the R.A.F. instructional film "Fighting Unarmed" was then shown, and this was followed by a "surprise item," which was a series of physical training exercises performed by the recruits accompanied by the band of the R.A.F.

Correspondence

A Fair Deal for Medicine

SIR,—The Government are committed to a comprehensive medical service available to everybody from conception to the grave. We welcome the assumption, which indeed is unassailable. What the Government ostensibly are not committed to is the exact form the service is to take. Therein lies our danger and our opportunity. The danger is that if we do not see the vital issues clearly and quickly, and do not present them with determination and unanimity, eschewing such thoughts as "anything is good enough for the general practitioner" and "the consultant is well able to look after himself," we may find ourselves fettered with uneasy chains. The opportunity, which may not recur for a thousand years, is that we can, if we will, evolve such a service as will testify to the honour, dignity, and usefulness of the whole medical profession. We are anxious to give society a fair deal, and we ask from society a fair deal in return. The essence of that fair deal can be concentrated under the title of spiritual freedom and economic assurance for the service and the individual.

Spiritual Freedom.—The medical profession should be so constituted (1) that any member, within the limits of his ability and character, can rise to the highest position in medicine and society in general, and that, no matter what his status, he can perform his legitimate medical duties and consult with any other member as a colleague and in a spirit of equality without fear or favour; (2) that in the organization of the medical service the decisions on matters of purely medical practice—e.g., teaching, research, hospital, consultant, and general practice—should be in the hands of predominantly medical committees, and that the decisions on matters of medical management—central, regional, or local—should be in the hands of committees on which medical men are adequately represented. I am convinced that the preservation of this professional and individual independence is compatible with wise State control.

Economic Assurance.—In general terms, the remuneration of the individual should be sufficiently generous to ensure his dignity and confidence in whatever society he finds himself. No patient likes his doctor's mental and material garb to be inferior to his own. The failures of medical practice in the past and the necessity for its reorganization in the future can be viewed from two aspects: (1) the inability of the general public individually to afford payment for their complete medical requirements; (2) the inadequate remuneration to doctors per patient, whether private or insured, which compels the busy doctor to be too hurried, particularly in thickly populated areas, and makes him fail to divide his time in proper proportion between individual patients, study, family duties, recreation and travel, etc., and civic responsibilities. In other words, there are too few doctors, the majority of whom are too busy attending to too many patients who are individually too poor to provide reasonable remuneration to those doctors. The poorer patients, including most of the middle classes, cannot individually be expected to bear the entire burden of their medical requirements. The answer is some form of insurance by contribution or taxation (*vide* the Beveridge report).

From the medical side payment can be by salary, capitation fee, or item of service. If the salary were adequate and provided for automatic increase according to the standard of living—and by living I mean not merely an arithmetic addition according to the cost of food (for man does not live by bread alone)—it would be the method most easily administered. It would allow of more ready co-operation between doctors in obtaining time for postgraduate study, running of health centres, holidays, and so on, and would replace the competition for patients by a competition for improvement in work. Any salaried system must not be based on the rigid Services model. Those doctors now in the Forces have full knowledge of that system, and they should have a say in the final judgment. This, of course, is not possible till after the war.

The Medical Planning Commission has recommended a combination of salary, capitation fee, and private practice. Let us beware that each item is not used as a lever to beat us down on the next, so that we would get a very small salary, a poor capitation fee, and practically no private practice.

To sum up, I think it is time that we adopted some purely medical aims on the lines suggested by Dr. Geoffrey Bourne (Feb. 20, p. 227) and applied generally, as I have sought to do under the heading of spiritual freedom. The Beveridge report is remarkable for its powerful presentation—concise, clear, and intrinsically fair. Could we not get Sir William Beveridge to examine our case, interview our divergent commissions, associations, unions, societies, and committees, and some representative individuals, and edit a medical report for our consideration? Failing this, could we not at least get him to address a general meeting of the B.M.A. on the subject of the medical services of the future, for he must have many recondite ideas and we might see a light?—I am, etc.,

London, N.2. G. W. M. MACKAY.

A National Medical Service

SIR,—The most disquieting feature of the statements so far made by the Government spokesmen is unquestionably that they "have made it clear that the responsibility for administering such a service is to devolve on local bodies." (*Journal*, March 20, p. 354.) This is a horrible outlook for the profession, as one can foresee that within a short time we should all be under the jurisdiction of our local medical officer of health. Such a setting up of "medical gauleiters" would indeed be a disaster for all practitioners. If there must be a State service then let it be administered centrally, so that we are all in the same boat, and not subject to the whims of local bodies.

It seems a great pity that the representatives of the profession who are to discuss the national service with the Minister of Health were not elected by a free ballot of the profession as a whole, instead of being proposed beforehand, no mention being made of who did the proposing. However, let us hope that our representatives will bear in mind when they meet the Minister of Health that he has already dealt the profession the worst "smack in the eye" that we have ever suffered by raising the income limit without prior consultations; also that they will not be led away by all the specious promises which are now being made and which are given such emphasis in the *Journal*. Specimens are: ". . . The Government, in framing any time-table, will not forget that many of the profession are serving over-seas" . . . "the Government has declared its intention not to spring surprises in unilateral action" (*Journal*, March 20, p. 354) . . . "the discussions will take place not on the basis of any preconceived plan of the Minister but 'from the ground'" (p. 359). There is a false note about these declarations and they certainly seem far removed from our experiences in dealing with the Ministry of Health on previous occasions.—I am, etc.,

Lincoln. G. A. BAGOT WALTERS.

Health Centres

SIR,—Dr. W. Edwards's semi-humorous letter (*Journal*, March 27, p. 398) is very disturbing. He is unaware of the nature of the proposed health centres. They will not be glorified out-patient departments. There was never any thought that they should in the least interfere with the correct treatment of sick people. They are to be places where general practice can be carried out under better conditions than at present. There would never be any question of his "little Audrey" having to go to the centre when she should be visited in her own home. To jeer at the white-coated doctor is rather reminiscent of the days when the same jibes were made at the sterile gown by the devotees of the filthy frock-coat.

It is quite reasonable to assume that health centres are not ideal in all areas, but in the great majority they will be an inestimable boon to the patient and the doctor alike. In this area we hope to establish an experimental health centre where the doctors will take their practices, lock, stock, and barrel, and do all their work therefrom. There will be a complete 24-hour service, and at the same time the doctor will get adequate rest. We intend to do only general practice, but we hoped so to improve our work that medicine will have for us that same intense interest that it had when we started out to practise our art. We are quite sure that at health centres we shall be able to take our rightful place in the world of prevention of disease by doing general practitioner research. It is impossible in the space of a letter to go into the full organization and scope of health centres, but since such ignorance of the subject is abroad I think a full-scale article is called for. Until that has been published may I appeal to would-be correspondents to hold their fire?—I am, etc.,

Yardley. ARTHUR BEAUCHAMP.

The G.P.'s Part in Planning

SIR,—May I as a G.P.'s wife write in support of Mrs. P. M. Beauchamp, whose letter you published on March 20. I am sure that as a class we G.P.s' wives will welcome a health service worked from centres instead of our own homes. For years we have been slaves to the telephone; and in these increasingly difficult days we are slaves not only to that non-stop instrument but also to the front-door and surgery bells. We, like many others, were forced to take an enormous old house in a bad state of repair. It is impossible to get servants, and I am now saddled with this nightmare until such time as some heaven-sent scheme for centres will release us from this eternal drudgery.

My husband joined the R.A.M.C. at the beginning of the war, and we have a locumtenent and his wife in the house. But for her presence here I should never be able to leave the place; as it is we take turns and consult each other as to convenience when we want to go out. Should one of us have an engagement then the other *has* to stay in no matter what other attractions may offer. I leave it to the imagination as to what holidays are like. Life is rapidly becoming intolerable for us. The G.P. is the only man expected to be on duty night and day year in and year out. It is time that a civilized community realized this and released these overworked men and their wives to enjoy a little legitimate and regular free time, and allow them the common privilege of choosing where and how they shall live.—I am, etc.,

M. ST. CLAIR MACKENZIE.

Kew Gardens.

The G.P.'s Part in Planning

SIR,—In the *Supplement* of April 3 (p. 42) Dr. Leslie Hartley, in support of his personal view, has quoted an extract from the Prime Minister's broadcast of March 21. May I draw everyone's attention to another extract from that broadcast? "Therefore you must rank me and my colleagues as strong partisans of national compulsory insurance for all classes, for all purposes, from the cradle to the grave." I think the little word "all" is very significant.

At the Representative Meeting in London on March 31 we were told that the Ministry of Health had taken its "eye off the ball" long enough to present the representative committee with a proposed scheme for medical services. We were given to understand that the scheme was so severely criticized by that committee that the Minister withdrew it, and we are not likely to hear any more of that particular one.

Perhaps selecting specific phrases from their contexts is a dangerous game in arriving at what a particular politician means. In this connexion I should like to refer to the letter of my friend Mr. Steele in the same issue. I was, unfortunately, prevented from meeting Sir John Jarvis, but I really am astounded to hear that our contribution to the world's problems is to be compared with "a very small drop in the bucket of post-war problems and expenditure." If so, I most heartily endorse Mr. Steele's suggestion that all study groups should make great efforts to meet their members of Parliament, if only to instruct and explain matters to them. After all, they are laymen and may consider that our work consists of a bottle of medicine, an operation, and—with a flourish of trumpets—diphtheria immunization; whereas general practitioners have for generations been labouring in the field of higher medicine, by which I mean all and more than Mr. Churchill referred to under the nation's health and education in his broadcast.

What better body of men could there be to report on local housing conditions than an active group of practitioners working under conditions visualized in the draft interim report? Practitioners have in the past been frustrated in such work—although they have been acutely aware of the need for it—by constantly having their attention and energies diverted into unproductive drudgery.

Finally, there is one aspect of this discussion which has forced itself upon me. The panel system was a "Departmental measure." Such success as it has achieved in the past is due almost entirely because the working of it has lain in the hands of general practitioners, 99% of whom are honest craftsmen. It is a poor workman that blames his tools, and in this lies the panel success. Would it not be far better in the future for medical men to plan a scheme that ensures that the public has real attention and care? Then let the scheme be presented to the Departmental authorities and bureaucrats, and let them devise Departmental rules that will fit our scheme, and not the other way round as was done in the National Health Insurance panel scheme. Whatever form the new practice takes let us insist, "These are the tools. Give them to us. And we will tackle the job."—I am, etc.,

TERENCE TURNER,

Godalming. Chairman, Guildford Study Group.

Highlands and Islands Medical Service

SIR,—It is to be hoped that the Scottish Representative Committee will take steps to acquaint themselves very fully with the conditions prevailing in the island practices of the West and North of Scotland, where, at the moment at least, an assistantship is less remunerative than it would be in the South. There are not too many doctors who would be willing to make the sea passages in rough and stormy weather that the island medical man is called on to do, and that in a small fishing boat for 20-odd miles; and the earnings of such a practice is gross £650, out of which come drugs, house, car, boat, etc.—I am, etc.,

Shetland Isles. M. M. C.

The Home Office announces that Dr. Alec Gordon Douglas Gavin of London, S.W.16, Dr Ian Fleming McLeod of Stirling, and Mr. Oswald White, dentist, of Bedford, are no longer authorized to be in possession of or to supply dangerous drugs.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W C—*Mon.*, 4 p m. Mr. J. C. Ross Injuries of the Urinary Bladder. *Wed*, 4 p m Mr C. R Greene: Frost-bite and Kindred Conditions *Fri*, 4 p m. Mr. S M. Cohen: Traumatic Arterial Spasm.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION—At B M.A. House, Tavistock Square, W.C, *Thurs* 5 p m Subject Some Therapeutic Uses of Endocrines in Obstetrics and Gynaecology.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, W.—*Sat.* (April 17) 2 30 p m. Major Marjorie Bolton: Sulphonamide Treatment of Gonorrhoea in Women.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.—Mon, 4 p m. Pathological meeting 5 p m Discussion.

SOCIETY OF THORACIC SURGEONS.—At Royal Society of Medicine, 1, Wimpole Street, W., *Wed*. 2 p m: First-aid Treatment of Chest Wounds and Injuries; and Early and Late Treatment of Retained Foreign Bodies. *Thurs.*, 9 30 a.m. Role of the General Surgeon in Treatment of Chest Wounds in Forward Areas. 2 p.m Treatment of Pleural Empyema.

B.M.A.: Branch and Division Meetings to be Held

GLASGOW AND WEST OF SCOTLAND BRANCH—At Institution of Engineers and Shipbuilders in Scotland, 39, Elmbank Crescent, Glasgow, Wed, April 14, 3.30 p.m. Prof. J M Mackintosh: Medicine and the Problem of Unemployment.

NORTHERN COUNTIES OF SCOTLAND BRANCH.—At Air Cadet Corps Hall, Bank Street, Inverness, Mon, April 12, 6 p m. Dr R L Kelham and Capt. A Maxwell. Amputations and Limb Fitting All medical practitioners in the area of the Branch are invited

NORTH OF ENGLAND BRANCH—At Newcastle General Hospital, Thurs., April 15, 7.15 p.m. Clinical demonstrations in Ward A1. Short papers by Dr. George Davison: Jaundice; Mr. J Collingwood-Stewart: Injuries of External Semilunar Cartilage; and Mr. Linton Smith: Sterility All members of H M. Forces serving in the area of the Branch are invited.

BIRTHS, MARRIAGES, & DEATHS

DEATH

MASTERMAN—In Jerusalem, Palestine, Ernest W. Gurney Masterman, M D, F R.C S, late Medical Superintendent, St. Giles Hospital, Camberwell, S E.5.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY APRIL 17 1943

SPECIAL REPRESENTATIVE MEETING

PROPOSAL FOR DISCUSSIONS WITH GOVERNMENT

The Special Representative Meeting, following the Joint Conference of members of the Representative Body and of the Panel Conference,[1] was held on the afternoon of March 31. Dr. PETER MACDONALD of York was in the chair.

The principal motion on the agenda, to which there were a large number of amendments, was a recommendation of the Council affirming the willingness of the British Medical Association, with certain important provisos, to co-operate in the preparation of a scheme for comprehensive health and rehabilitation services should Parliament decide to accept the assumptions of the Beveridge report and put into operation its proposals, taken as a whole. The CHAIRMAN OF COUNCIL (Mr. H. S. Souttar) formally moved this recommendation, but said that circumstances had changed since the Council formulated it, and in view of the debate in the Joint Conference a different form of resolution might be preferable.

Dr. H. GUY DAIN, who had been chairman of the Joint Conference, explained that it was not competent for an outside body such as the Joint Conference to bring forward a proposal to the Representative Meeting, and therefore in his own name, with Dr. J. B. Miller as seconder, he proposed the tripartite resolution which the Joint Conference had adopted, and technically it would be an amendment to the Council's proposition. He moved accordingly the first section of the resolution:

"That the Government's invitation to enter into discussions without commitment be accepted."

This was agreed to without dissent.

The Representative Committee

Dr. DAIN then proceeded to move the second section:

"That a committee representative of the profession as a whole should, in response to the Government's invitation, now enter into discussions with representatives of the Minister of Health on 'a scheme for comprehensive health and rehabilitation services, for the prevention and cure of disease and restoration of capacity for work, available to all members of the community' (Assumption B of the Beveridge report), in the light of the following undertakings now given:

"(*a*) That, at the conclusion of the discussions and at the appropriate time or times during the discussions, but in any case before negotiations open and before any proposals are submitted by the Government to Parliament, the full machinery of the Association, including the Council and its Committees, Groups, Panel Committees, Divisions, and the Representative Body, will be used to consider the Government's proposals and to decide the Association's view thereon.

"(*b*) That every practicable step will be taken to give all members of the profession, whether members or non-members of the Association, an opportunity to express their views and in particular that every practicable step will be taken to give to members of the profession on service an opportunity of expressing their views, to assess those views, and to present them to the meeting or meetings of the Representative Body called to consider any proposals by the Government."

Dr. J. B. MILLER, in seconding, said that in passing this resolution, the Association was mindful of its great history and traditions. Practically every great improvement in the health services had been ventilated at the Annual Meetings of the Association, in some cases years before it was brought about. The foundation of the Ministry of Health, for example, was advocated by the Association fifty years before it was established. The reform of the Poor Law, the institution of the school medical service, and many other important innovations really had their birth in Association discussions. It was only right, therefore, that when this great scheme for comprehensive services was before the country the Association should be in at the very beginning. The CHAIRMAN pointed out that the effect of passing this motion would be that a large number of the amendments on the paper, which were to the Council's original proposition, would fall to the ground.

Dr. C. I. SCHIFF (City of London) said that if some of these amendments were not taken the result would be a feeling of frustration in the Divisions. Dr. D. L. S. JOHNSTON (Halifax) said that the question centred on the phrase "available to all members of the community." He desired to move that the committee which went into discussion with the Minister should do so on the understanding that the Association was not committed to a comprehensive scheme. Mr. H. J. MCCURRICH (Brighton) asked whether such a motion would not be equivalent to rescinding the resolution in favour of the inclusion of the whole community which was carried by a small majority at the last Annual Representative Meeting, and for this purpose two months' notice would be necessary. The CHAIRMAN said that that was overruled by the by-law which authorized the calling of a Special Representative Meeting. Eventually, however, Dr. JOHNSTON withdrew his motion.

The amendment moved by Dr. Dain was carried, with four dissentients, and became the substantive motion, and as such was carried.

Dr. C. A. BINNEY (Reigate) moved that approval of the part of the Beveridge report which applied to the medical profession should be postponed until after the war, the reason being the impossibility of obtaining, in present circumstances, the views of the large number of doctors now serving with the Forces. It was not a fitting time, he said, at the height of the greatest struggle in our history, to divert our thoughts and energies from the supreme task of getting on with the war. The CHAIRMAN said that such a motion could be put up at an Annual Representative Meeting when decisions were to be taken, but in the present stage of discussion he did not think it was appropriate.

Dr. DAIN, in reply to some further discussion, said that the word "available" did not necessarily mean "provided free of cost." Some of those who had amendments on the paper seemed to fear that the time spent in the Divisions in considering detail would be lost. There need be no such fear. The opportunity of using the opinions of the Divisions would arise at a later Representative Meeting, and it would then be not only competent but very desirable for these to appear on the paper again as an expression of Division opinion. He also explained that the "undertakings" mentioned in the resolution were between the Representative Body and the committee which was set up to do the work, but the word also referred to an undertaking given at the preliminary meeting by the Minister of Health that such a course would be adopted by him.

Composition of the Committee

Dr. DAIN then moved the third part of the resolution which had been carried in the Joint Conference:

"That the composition of the representative committee, as reported in the statement published in the *Journal* of March 20, with the additions announced at this meeting, be approved."

He again reminded the meeting that this was a discussions committee, not a negotiations committee, and it had no power to commit the Association in any way. Its task would be to explore the possibilities of a national health service scheme on the understanding that the matter would in any case come back to the Representative Meeting. Approval was asked on the distinct understanding of the limited functions of the committee and on the undertaking that opportunity would be afforded for its reconstruction when a negotiating committee was required.

Dr. G. DE SWIET (Kensington) said that the number of amendments which had been ruled out of order proved that there was a good deal of uneasiness in the minds of the profession about the way in which this body had been chosen. Uncomplimentary remarks had been made in some quarters about the "old gang." It was true that this was not to be a negotiating body, but how could they be sure that another crisis of urgency would not arise and the committee become a negotiating one before the rank and file could do anything about it? The meeting ought to express its opinion on the composition of this body and not be stampeded into accepting this list of names without further scrutiny. Dr. **Johnston** (Halifax) said that he had been impressed by the assurances given that the committee would not undertake negotiation, but he felt that a protest should be made against this arbitrary selection, especially at a time so near to the Conference. The choice might have been delayed until the Conference had indicated some preferences. Accordingly as a matter of protest he moved a resolution of lack of confidence in the present constitution and method of selection of the committee. Dr. J. **Beck** (Glasgow) stated that many of the members proposed for this committee had preconceived notions as to the form of practice which should be adopted by the Government; some were in favour of a whole-time State Medical Service. Dr. **Dain** said that the meeting either should turn down the committee altogether and set up a new one or should have complete confidence in it. To agree to the committee and yet to withhold confidence, as the Halifax motion proposed, was surely the most unsatisfactory course of all.

---

[1] See last week's *Supplement*, pp. 43-6.

The Halifax amendment was lost, with only about a dozen hands being held up in its favour, and Dr. **Johnston** then withdrew certain other amendments standing in the name of Halifax, calling for a higher proportion of general practitioners and recommending that the practitioner representatives on any committee negotiating with the Minister of Health should be elected by a plebiscite from the Divisions. The representatives of Middlesex, however, urged an increase in the number of general practitioners on the committee, to which Dr. **Dain** replied that in a body which now numbered 39 there were 19 general practitioners, and having regard to the diverse medical interests which had to be represented it seemed to him that the general practitioners were a very solid body and corresponded fairly well with the proportion of general practitioners on the *Register*. A motion to increase the number of general practitioners was rejected.

Dr. J. A. **Moody** (Stratford) desired additional representation for public health, industrial medicine, and men on service, but in view of assurances that these interests would not be lost sight of he withdrew a motion he had on the paper to that effect. Dr. **Melville Hiley** (North Glamorgan) urged a larger representation of practitioners in whole-time work in general and special hospitals. Dr. **Dain** explained that whenever problems relating to specialist groups were under discussion they would be referred to the Association Groups, and subcommittees would be set up in which these interests would be represented. A motion to include this representation in the discussions committee was lost.

The motion approving the composition of the committee was carried, with four dissentients, and the recommendation as a whole which had come from the Joint Conference was put to the meeting and again carried, with little or no dissent.

A proposal that negotiations should be conducted by experienced legal representatives was made by Dr. **Howie Wood** (Isle of Wight), but after some debate he withdrew it as the question did not arise during the preliminary discussions, but only when the stage of negotiations was reached.

Safeguards for the Profession

Dr. A. F. **Wilkie Millar** (Edinburgh) moved a lengthy resolution which, *inter alia*, laid down the following essentials as regards character, terms, and conditions of the medical service:

(1) That the organization be such as to conserve the scientific and political freedom and the independence of the profession;

(2) That the administrative structure should secure that the interest of the profession be safeguarded by the establishment of statutory bodies, to which doctors would have access and on which they would be represented; and

(3) That the terms and conditions of medical service be determined by negotiation and agreement with the profession.

The motion further laid it down that in the best interests of the citizen, and for the maintenance of a high standard of medical service, private practice should continue to operate concurrently with a publicly provided service, and that a field for private practice could be achieved in accordance with the Beveridge report by the following proposals:

(1) That the proportion of contributions to the social insurance fund to be assigned to the health departments should be applied towards providing specialist, institutional, and rehabilitation services for 100% of the population.

(2) That a domiciliary medical service financed by the Exchequer be provided for that section of the population whose income is below a certain level, but that the section with a higher income should obtain this service on a private basis from doctors within and without the scheme.

(3) That those members of the community who decide not to avail themselves of the benefits of the specialist, institutional, and rehabilitation services open to them should not be precluded from obtaining these services from consultants and specialists who may be operating within the scheme, paying for these services privately.

He asked that this motion should be referred, through the Council, to the representative committee.

Dr. J. A. **Ireland** (Shrewsbury), in seconding, took occasion to complain that the agenda of the meeting had been side-tracked. He would not put it beyond the Minister himself, knowing the present meeting had been called, to have caused the letter by Sir John Maude, Secretary to the Ministry, published in the *British Medical Journal* of March 20 (p. 359), to be sent, so that this side-tracking might take place. Representatives had come at considerable inconvenience to find the agenda washed out. The only urgency was political, on the side of the Minister. Now the only course was to agree and to withdraw a number of matters which could have been usefully discussed at the present meeting.

Dr. **Dain** said that as one concerned in the arrangements he took the strongest exception to these remarks by Dr. Ireland. Instead of the meeting spending its time on detail, which would come forward later, a number of important decisions had been made and the time had been very well spent. Dr. J. B. **Jessiman** (Worcester) said that, if one was to believe the Press reports the Minister had made the statement that the public would have a family service with free choice of doctor. He suggested that the Minister had been guilty of a breach of faith in divulging details of the service of the future, and that the assurance that no plan had been preconceived was a scrap of paper.

Prof. R. M. F. **Picken** pointed out that one of the paragraphs in the Edinburgh motion (referring to people with a higher income obtaining service on a private basis) was contrary to the decision of the Annual Representative Meeting last September—the decision about which they were all rather uneasy because the majority was so small. Would it be proper for the Representative Body to commit itself even to the extent of referring this to the Council? The **Chairman** said that the proposal, if carried as a reference to the Council, did not commit the Representative Body to anything.

As a reference to the Council the motion was carried.

Dr. E. E. **Glenton** (Warrington) asked that practitioners should be kept fully informed of the progress of the negotiations. The **Chairman** said that that assurance had been already given.

Other relevant matters on the agenda were referred to the Council, and the Special Representative Meeting concluded.

SPECIAL PANEL CONFERENCE

The Government's Invitation

A Special Conference of Representatives of Local Medical and Panel Committees was held in London on March 31, following the Joint Conference and the Special Representative Meeting. Its purpose was to consider the Government's invitation to enter into discussions on a scheme for comprehensive health and rehabilitation services (Assumption B of the Beveridge report). Dr. J. A. **Brown** of Birmingham was in the chair.

Dr. H. **Guy Dain**, chairman of the Joint Conference, brought forward the recommendation carried by the Joint Conference and by the Special Representative Meeting, which has been published *in extenso* in the reports of those assemblies. The first section, that the Government's invitation to enter into discussions without commitment be accepted, was agreed to without dissent. The second section was then moved, that a representative committee should enter into the discussions, but that at appropriate times, and in any case before negotiations were opened, the full machinery of the Association should be used to consider the Government's proposals, and that every step should be taken to give all members of the profession an opportunity to express their views. This also was agreed to by an overwhelming majority.

The chief discussion centred around the proposal that the composition of the representative committee as reported in the *Journal* of March 20 (p. 359) be approved.

Claim of the Medical Practitioners Union

Dr. **Gordon Ward** (Kent) said that at the Joint Conference, in asking that the Medical Practitioners Union should be given representation on the committee, he had stated that the Union had between 5,000 and 6,000 members. This figure had been challenged by Dr. Gregg. He had now got the exact figures for the end of 1941—the latest date available—on which the Union had paid affiliation fees to the Trade Union Congress. The actual number was 5,327. Dr. Gregg had also stated that the Union had been a hindrance rather than a help at the Court of Inquiry into the capitation fee. But in fact the chairman at that inquiry had gone out of his way to compliment the Union on the way it had presented its case, and a chart which it produced dealing with the cost of living was almost immediately taken over by the B.M.A. representatives. There were differences of policy in the profession, but if there was to be a united front the upholders of different policies must sit round the table together.

Dr. R. W. COCKSHUT (Middlesex) said that to agree to this request of the M.P.U. would be a disaster. It was a body in favour of a full State salaried service, a thing which to the vast majority of the profession was abhorrent.

Dr. S. REVELS (Derby) moved that, in view of the desirability of maintaining complete co-operation of all sections, the M.P.U. be represented. Dr. C. F. R. KILLICK (Somerset) said that he was not a member of the M.P.U., but he thought other organizations must be treated fairly. Dr. F. M. ROSE (Preston) also thought that room should be found for minority opinion. He disagreed with a great deal of M.P.U. policy, but now a chance presented itself to bridge a most unfortunate gap. Dr. A. BEAUCHAMP (Birmingham) and Dr. HOWIE WOOD (Isle of Wight) spoke against the representation of this organization.

Dr. E. A. GREGG (chairman of the Insurance Acts Committee) said that he severed his connexion with the M.P.U. some years ago because he was satisfied that the organization was more interested in getting membership than in the welfare of the profession. As to the figures, the return for 1941 showed subscriptions amounting to £5,833. This with a two-guinea subscription worked out at very much less than the 5,000 or 6,000 membership which had been suggested. He placed no reliance on either the figures or the undertakings of these people. They would pursue the same course as they had done all along of endeavouring to discredit the B.M.A. in the eyes of the Ministry and everyone else. Nor had he the slightest fear of their negotiations—or whatever words they like to use—with the Ministry of Health, because he knew how little weight the Ministry would attach to their opinions. No one was more anxious for unity than himself, but a false unity achieved because of a desire to cover up differences which could not be covered was a source of danger.

Dr. GORDON WARD replied that Dr. Gregg was formerly president of the Union. After a time he was converted to other beliefs, and there was no one so fierce as the convert. The figures which he (Dr. Ward) had given were figures certified by the auditor. But to him the interests of the profession were more important than any sectarian interests, and it was for the sake of professional unity that he suggested it was important that such a body as the Union should be represented.

The Derby motion to include the M.P.U. was rejected.

The Scottish Representation

Dr. W. JOPE (Lanarkshire) moved that it be remitted to Scotland to elect its own representatives on the committee, the number not to exceed six, and this was seconded by Dr. R. C. HAMILTON (Ayrshire).

Dr. DAIN said that three of the Scottish representatives chosen were the nominations of the Scottish Royal Colleges and the Royal Faculty. For the other three the chairman of the Scottish Committee of the Association, the chairman of the Scottish Insurance Acts Subcommittee, and the deputy chairman of the Representative Body had been chosen. He suggested that the Scottish representatives in the conference could serve no useful purpose by altering the committee except to satisfy some theory.

Dr. JOPE said that Scotland was thoroughly dissatisfied at having her representatives nominated for her. He begged that she might be allowed in a contented way to proceed in this matter and not be estranged at the outset. (A voice: "If Scotland is to choose her own people, why not England?")

The amendment to remit it to Scotland to choose her own representatives, the number not to exceed six, was carried.

Dr. W. ARNOTT (Oxford) urged that there should be representation of men on service. Dr. KILLICK (Somerset) said that rural practitioners were not fully represented. He was glad to learn that there was to be an additional representative from rural Wales, but there were parts of England in which there were special problems attaching to rural practice. If discussion was to take place between the representative committee and a subcommittee representing rural practitioners it would satisfy him.

The motion to approve the committee's composition, amended by the decision to remit it to Scotland to choose her own representatives, was then put and carried, and the recommendation from the Joint Conference as a whole, again with this Scottish amendment, was adopted almost without dissent. Dr. J. G. THWAITES (Brighton) moved that in the event of negotiations failing to secure conditions satisfactory to the profession the Council should have a plan ready to carry on the treatment of the sick without participation in the Government plan. This was carried.

The Insurance Capitation Fee

Dr. J. R. LANGMUIR (Glasgow) moved:

> That a prior condition to any negotiations between the Government and the medical profession regarding the new medical service is the immediate settlement of the question of the basic capitation fee for the period that National Health Insurance has to run.

He said that this expressed the unanimous opinion of the Glasgow Panel Committee. The capitation fee dispute preceded by a long time the Beveridge report, and in Glasgow they had little confidence that the atmosphere of the negotiations on the latter would contain anything but suspicion and misgiving until the former was cleared out of the way.

Dr. BEAUCHAMP (Birmingham) said that any new negotiations must be separate from the whole question of the capitation fee. He was not satisfied with the position with regard to the capitation fee, but if the new negotiations were to take place from the ground up, this was pretty nearly the top story.

The motion was supported by Dr. J. BECK (Glasgow) and opposed by Dr. F. E. GOULD (Birmingham), who said that if by negotiating now for an insurance capitation fee an extra sixpence or shilling was obtained, this would be made the basis for negotiation of the entire new scheme and would be a very bad start.

Dr. PETER MACDONALD hoped that the negotiations with the Ministry would have no relation to the present capitation fee. That fee for general practitioner service would be grossly inadequate for any new service under the social security scheme.

Dr. GREGG said that he had a good deal of sympathy for Glasgow's point of view, for they were all smarting under a sense of frustration in that they had step by step presented to the Minister their soundly based claims and these had been rejected by him. But one of the things they had said to the Minister when he mentioned the Beveridge report was that the report had nothing to do with their action on the capitation fee, and he did not think it was desirable to wrap up their case with this new matter. That would be only to lay up for themselves a store of trouble.

The Glasgow motion was lost.

Compensation to Practitioners

A motion by Norwich was on the paper, that the Government be informed that to obtain the willing co-operation of the medical profession in any future scheme of medical services, it is fundamentally necessary to deal properly with the question of adequate compensation for loss of goodwill and capital.

Dr. GORDON WARD said that it was not only compensation which was wanted but also pension on compulsory retirement.

Dr. DAIN said that on the second occasion on which the Representative Committee met the officers of the Ministry Sir Wilson Jameson stated that the Government accepted the principle of compensation in the matter of capital value of practices. He did not go any further than that, and they at the present moment, on their side, were engaging actuaries in the endeavour to establish what sort of values should be payable as compensation.

Dr. N. J. COCHRAN (Burton-on-Trent) said that the statement just quoted as having been made by the Chief Medical Officer of the Ministry, along with other statements, suggested to him that the Ministry had at the back of its mind a State medical service. Dr. A. W. WESTON (Dudley) said that he was amazed at the "credulity" of Dr. Dain and Dr. Gregg in accepting the verbal statement that the matter of compensation would be kept in mind. After considering the treatment which the profession had had meted out to it by the Ministry of Health could any reliance be placed on a verbal assurance? Practitioners wanted it in black and white that they were not going to lose what they had worked for. Proper and adequate compensation should be insisted upon as a preliminary condition.

Dr. GREGG said that he was opposed to a whole-time service and would continue to oppose it. Therefore he hoped that this and similar resolutions would not be dealt with, as they might be supposed to indicate a direction in which their minds were working.

It was agreed to pass to the next business.

Dr. A. W. HALL (Hampshire) moved that contributions to health services should not be based on a flat rate but should be proportionate to income, and that the health services should be administered by a separate body on which the medical profession was adequately represented. A flat-rate assessment, he said, would preclude doctors from obtaining a reasonable remuneration.

Dr. **Gregg** said that it was clear from the Beveridge report that only a small portion would come from contributions directly related to health services, and that a very much larger amount would come from Treasury sources. But this was a point for the future in connexion with any negotiations which might take place, and could be left until a time came which was more appropriate for dealing with it.

The motion was withdrawn.

Insurance Practitioners and their Contracts

This concluded the motions on the paper relating to the Beveridge report and the ensuing conversations, but a motion stood in the name of Lancashire:

> That this Conference, being disgusted with the reply received from the Minister of Health, now calls upon the Insurance Acts Committee to consider the advisability of recommending insurance practitioners to terminate their contracts.

Dr. T. J. **Costello**, in moving, said that Lancashire went away from the last Panel Conference feeling very happy because of the strong resolutions which had been passed, but they were "horrified" when they found afterwards that the Insurance Acts Committee had not exercised the full powers given to it. It was urged upon them that for patriotic reasons they should not resign their contracts. It was not fair to place doctors in a quandary by asking them to decide on patriotic grounds when the Ministry had had no qualms on patriotic grounds about putting them in that quandary. He begged that this matter be finished with once and for all. Unless they were prepared to send in their resignations it was only a waste of time.

Dr. **Gregg** replied by quoting the last letter which the I.A.C. had sent to the Minister (*Supplement*, March 13). It was stated to the Minister in that letter that consideration of the national interest had deterred them from taking cerain action. They had expressed their dissatisfaction that he should have taken advantage of the public-spirited attitude of the medical profession. But they had not said that that deterrent influence would continue to operate. It would be a matter for each Panel Committee to determine whether, in view of this sustained resistance on the part of the Minister to what they believed to be a good case, they should continue to feel so deterred. It was not a question of saying in indignant haste: "We will resign," but of proceeding with deliberation and on the basis of organization in the different areas. If Panel Committees reported back to the I.A.C. that they were going to stand fast, and that their men were prepared to resign, the I.A.C. was prepared to carry this thing through to the very end. (Applause.) But it would need substantial support from the panel areas. For his own part he would feel honoured if it should fall to his lot to say to the Minister: "The medical profession has finished with the Insurance Act in view of the way you have treated us." Panel Committees would receive a communication from the I.A.C. along those lines.

In view of Dr. Gregg's statement the Lancashire resolution was withdrawn, and the Conference concluded.

BRITISH MEDICAL ASSOCIATION

Election of Members of Council

Notice is hereby given that nominations of candidates for election as members of Council, 1943–4, by the following Branches and by Public Health Service members must be forwarded in writing so as to reach me not later than Saturday, May 29, 1943.

Twenty-two Members by Branches in Great Britain and Northern Ireland

	No. of Members of Council to be elected by Group
Group A.—North of England	1
Group B.—East Yorks, Yorkshire .	1
Group C.—Isle of Man; Lancashire and Cheshire	2
Group D.—Derbyshire; Leicestershire and Rutland; Lincolnshire; Nottinghamshire	1
Group E.—Bedfordshire; Cambridge and Huntingdon; Essex; Hertfordshire; Norfolk; Northamptonshire; Suffolk	1
Group F.—Berks; Bucks and Oxford; Birmingham; Staffordshire	1
Group G.—North Wales; Shropshire and Mid-Wales	1
Group H.—South Wales and Monmouthshire	1
Group I.—Metropolitan Counties ..	4
Group J.—Bath; Bristol and Somerset; Gloucestershire; Worcestershire and Herefordshire	1
Group K.—Dorset and West Hants; South-Western Wiltshire	1
Group L.—Southern; Surrey	1
Group M.—Kent; Sussex	1
Group N.—Aberdeen; Dundee; Northern Counties of Scotland; Perth	1
Group O.—Edinburgh; Fife	1
Group P.—Glasgow and West of Scotland (Glasgow Division)	1
Group Q.—Border Counties; Glasgow and West of Scotland (Five County Divisions), Stirling	1
Group R.—Northern Ireland	1

Candidates must be nominated either (*a*) by a Division or (*b*) by not fewer than 3 members of the Branch or Branches in the Group. The nominations must be on the prescribed form, a copy of which can be obtained on application to me.

Public Health Service Members

Two members of Council are nominated and elected by members of the Association employed in the Public Health Service as defined in By-law (3). Candidates must be members of the Public Health Service as so defined.

A notice will be published by the Council in the *British Medical Journal Supplement* on June 19, 1943, of the candidates nominated. Where contests occur voting papers will be issued on June 19, 1943, containing the names of all duly nominated candidates, from the Head Office, British Medical Association, Tavistock Square, London, W.C.1, to each member in the Group or to the Public Health Service members. A notice will be published by the Council in the *Supplement* of July 10, 1943, giving the results of the elections where there have been contests.

G. C. Anderson,
Secretary.

Branch and Division Meetings to be Held

North of England Branch.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thurs., April 22, 2.15 p.m. Clinical demonstrations in the Out-patient Department. Address by Dr. Freda K. Herbert. Investigation of Cases of Hepatic and Biliary Disease. All members of H.M. Forces serving in the area of the Branch are invited to attend.

Shropshire and Mid-Wales Branch.—At Royal Salop Infirmary, Tues., April 20, 3.30 p.m. Continuation of adjourned general meeting.

The Home Secretary announces that Andrew Thornton is once more an authorized person for the purposes of the Dangerous Drugs Acts, 1920.

PETROL FOR MEETINGS

The B.M.A. has represented to the Petroleum Department that doctors should be allowed to travel by car to medical meetings, such as meetings of B.M.A. Divisions, which will be necessary in connexion with the discussions between the Government and the profession on the comprehensive medical service envisaged in the Beveridge report. The Department has agreed that, where other means of transport are not reasonably practicable, doctors may use petrol granted for "professional purposes" for journeys to attend such meetings. This arrangement does not apply to regular meetings of Study Groups, but only to such occasional meetings as it may be necessary to arrange for consideration of specific proposals arising out of the central discussions with the Government. Regional petroleum officers have been authorized to grant an *ad hoc* issue of petrol for a journey of this kind when a doctor's normal allowance is insufficient to enable him to attend a meeting and his attendance depends on the use of his car.

H.M. Forces Appointments

ROYAL NAVY

Surg. Lieut. (Emergency) S. E. Cooke to be Surg. Lieut.-Cmdr. (Emergency).

Surg. Lieuts. S. E. Cooke and P. S. Edgecombe have been transferred to the Emergency List.

Royal Naval Volunteer Reserve

Surg. Lieut. R. M. Marshall to be Surg. Lieut.-Cmdr.

Prob. Temp. Surg. Lieuts. J. A. Sadler, J. W. Bringan, R. S. Smith, St. J. M. C. Birt, W. H. Yellowlees, A. J. Walton, J. F. Paxton, A. A. Murray, I. L. Maxwell, J. Lockie, G. W. E. Little, G. P. Hartigan, J. A. Cosh, S. N. Cole, E. J. W. Barnard, F. E. Fraser, J. Murphy, R. L. Norris, H. McColl, P. G. Dagleish, W. E. R. Budd, N. S. Daw, E. W. Guillaume, M. McFarlane, D. Micklewright, R. O. Wheeler, G. W. Burns, G. MacVicar, H. R. Claff, M. D. O. Plunkett, A. E. S. Wood, T. G. Griffith, and C. J. Thornberry to be Temp. Surg. Lieuts.

REGULAR ARMY RESERVE OF OFFICERS

Royal Army Medical Corps

Major P. Hayes, having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers, and has been granted the honorary rank of Lieut.-Col.

Major A. S. Cane, D.S.O., O.B.E., having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers.

DIARY OF SOCIETIES & LECTURES

Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.—*Mon.*, 4 p.m. Prof. J. E. A. O'Connell: The Vascular Factor in Intracranial Pressure and the Circulation of the Cerebrospinal Fluid.

Royal Society of Medicine.—*Mon.*, 4.30 p.m. Sections of Odontology and United Services. Members of the Section of Epidemiology and State Medicine are invited to attend. *Tues.*, 5 p.m. General meeting of Fellows. *Wed.*, 2.15 p.m. Section of Comparative Medicine.

APPOINTMENTS

Rubinstein, L. H., M.D., D.P.M., Temporary Psychiatrist, Derby Child Guidance Clinic and Chesterfield Children's Centre.

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

DEATHS

George.—Diane Adair, aged 5, on April 5, 1943, beloved daughter of Mr. and Mrs. Clive George, of Colindale, Heath Drive, Romford, Essex.

Sydenham.—At Walsall, on April 5, 1943, Frederick William Sydenham, M.D., F.R.C.S.Ed., 379, Harborne Road, Edgbaston, Birmingham.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY APRIL 24 1943

Correspondence

The B.M.A. and the Beveridge Report

SIR,—May I be allowed the publicity of your columns for the purpose of being immodest? The inherent modesty of the British is too well known, and in nothing before has it been so lamentably emphasized as, in the past and present discussions of medical planning and in the proposed obsequious attitude to the Beveridge plan. It is time for us to tell the planners of this "New (medical) Order," and the whole world if necessary, that the present system of British medicine is the finest in the world. The system provides adequate attention for every member of the community, however poor and friendless, whether through Public Assistance, the P.M.S., N.H.I., or private arrangement, and ensures them the services of a doctor who can hold his own in skill, honesty, and integrity against the graduate or licentiate of any other medical school in the world. The poverty of the patient does not deny him any essential medical service. It provides for the doctor a respected place in the community, and rewards his skill and initiative by increasing his practice and his income.

To encourage us to support plans for a new medical system it has been alleged lately by some people that the public is suspicious of us, and that we should endeavour to re-establish ourselves in its favour by bowing down in the House of Rimmon and accepting Sir William Beveridge's plan. Every doctor engaged in general practice knows in his heart that this is rubbish. The public has an almost exaggerated regard for the doctor and does not begrudge a skilful, conscientious, and kind practitioner any honour or reward. How often do we hear complaints of the present medical system or read in the papers of patients dying of neglect owing to its deficiencies? Such friction as does arise between doctor and patient is generated by the administration of the panel system, with its irritating regulations and impositions. Possessing initiative, resource, and intelligence, used to making decisions of importance and taking full responsibility for his actions, the doctor has all the very qualities which form the greatest barriers to advancement in the ranks of the Civil Service or any other State-controlled system.

Meetings all over the country have been called by the B.M.A. to give approval to prepared resolutions, which, in effect, say that we shall be ready to enter a comprehensive panel system embracing all members of the community, provided the Government negotiates with the profession for terms of service, and provided those who can afford it may obtain private treatment from doctors already under contract to give them a full service. The wording of this second proviso inflicts a serious indignity on the profession. Remuneration for contracted service is one thing, but payment for a preferential variation of the same service is what is commonly called "tipping." Hitherto, thanks to the support of private practice, it has always been possible to give the panel patients a service every bit as good as that afforded to private patients. It is difficult to understand the need for the second proviso. With regard to the first proviso, the events of 1911 and the more recent efforts by a most united and resolute medical front to obtain a reasonable increase in the panel fee should prove the futility of negotiation with the Government.

If the medical men of this country were growing rich on the spoils of incompetence and dishonesty the suggestion of a medical reformation would be hailed by the Press and public. As it is, the public does not appear dissatisfied with us, and our threatened attenuation and restriction can do no more than make political capital for some Party which wishes to boast that it has given the nation a new health charter. My very strong contention is that we must fight to maintain the present system for the good and the health of the community, and for the good of the profession, morally, scientifically, and financially.—I am, etc.,

St. Ives. E. C. ATKINSON.

The Profession and the Politicians

SIR,—It was refreshing to read the Insurance Acts Committee's letter to the Minister of Health (*Supplement*, March 20, p. 35), and I trust that this spirit will animate the Committee's present discussions and subsequent negotiations. If this fighting spirit is kept up, I have no doubt that all of us who have wavered in our faith in the I.A.C. will forget the past history of negotiations, and will back up the committee to the last ditch, and beyond if necessary. For too long have the decency and humanity of the medical profession been exploited by successive politicians, and the time has arrived to make a firm stand. It is to be hoped that the question of compensation for practices for those not wishing to join the scheme will be satisfactorily settled, as no doubt there will be a number of us who would not wish to cease to be "family doctors" and become mere civil servants, and be compelled to work on till, say, 65 years of age before "enjoying" a pension.

We must not be deterred in our fight by sloppy sentimentality, nor be impressed by such camouflage as "a charter of liberty for the overworked doctor," but deal like business men with a business problem; and keep always in our minds the fact that we fight not only for ourselves, but for the younger members of our profession on active service who are too busy to give serious consideration to this vital problem, but who look to us to see that they are not let down.—I am, etc.,

Blackburn. F. E. EDWARDS.

Medical Planning and the Elderly Patient

SIR,—Considerable alarm is spreading in the minds of the older section of the people on account of adumbrations of a reorganization of medical services, partly understood or misapprehended by them. The bogy is of some imminent change which will deprive them of the doctor they like and trust and hand them over to some impersonal roster or clinic. This fear is shared alike by the poor and the well-to-do. I myself, with some experience of a salaried medical service, am confident that such fears are groundless. I am sure that our negotiators, appointed by ourselves through the B.M.A., will be able to steer us between the Scylla of a cast-iron Civil-Service-controlled organization and the Charybdis of—well, things as they are. But one thing is clear: that the change-over must come gradually and piecemeal; the new service must feel its way, and there must be scope for the old-fashioned patient and doctor to exercise their right of choice. Doctors and always doctors, it is our duty to comfort our older patients with the assurance that no revolutionary changes will pass over the profession in their time at least.

One word more. The verdict of business men I have spoken to about future changes is always this: that they do not want their doctors run by either Civil Service or local government, and they have every confidence in the medical profession's ability to handle its own affairs in its own way to the benefit of the public.—I am, etc.,

Garelochhead A. GUTHRIE BADENOCH.

Preserving our Freedom

SIR,—I write in response to the excellent letter of Dr. Lindsey W. Batten (*Journal*, March 13), in which he speaks of the freedom we all want. It seems to me that a wave or miasma of State worship has spread over the country and infected our profession. Have the members visualized the future? A medical civil service monopoly organized and controlled by the State; every young man sent to fill the billet he is ordered to accept; no leave but at times fixed by the Department; no chance for a young man to travel or go to sea or study on the Continent unless he loses seniority for pension; no freedom to change from East London to Devonshire if he fee's inclined to do so and can afford it; salary, to judge by the payments of the Government so far, very likely to get lower, as it is always a minimum.

Sir, our profession, helpless, unpractical, and idealistic-philanthropic, is the servant of the people, but why should it be the slave of the State? The panel service, in which we are quite at the mercy of one man, against whom there is no appeal, is the result of the foolish terms we made in 1912. Imagine a time when the terms of service are rigidly enforced and tightened up and the remuneration cut down by a hard-driving

Minister, and remember we have no remedy. Can you see the members of the legal profession enrolling themselves as a State service? They know better.

Without this revolution, Sir, can we not depend on English evolution and compromise which have served us so well? The State is our servant. Let us serve the people and keep clear of the bureaucrats to preserve our freedom.—I am, etc.,

Fulham. Alex M. Ross.

5 Wed Journal Board, 1 45 p m.

B.M.A.: Meetings of Branches and Divisions

Belfast on the B.M.A.

At a meeting of the Belfast Division, held at the Whitla Medical Institute on March 3, the subject for discussion took the form of the question: "How can the wishes of the medical profession in Northern Ireland best be expressed, and how can the interests of the profession best be maintained?"

Dr. F. M. B. Allen, who opened the discussion, said it was not likely that the Government of Northern Ireland would be less sympathetic towards the Beveridge plan than was the Government of Great Britain. He urged the need for unified opinion, and stated that the B.M.A. was the agent and had the machinery for adequately expressing the views of the profession. Dr. Allen described his personal experiences of the B.M.A. in the Branch and as a member of the Council and of the Medical Planning Commission. He referred to the regard paid by Government Departments to the opinion of the Association and denied that it was "in the Government's pocket." He referred to the rapid action of the central secretariat in having the Beveridge report discussed by the various committees, and quoted the recommendation to the Representative Body which had been sent to the Divisions.

Dr. Robert Marshall said that it was so long since some of them qualified and were given the *Handbook* of the Association that they had forgotten a great deal of its contents. Some had never read it at all, and some did not belong to the Association. The *Journal* and the library were worth the annual subscription, apart from the Annual Meeting, but it was not for these only that he valued membership, but because the Association represented every section of the profession. Among its members were family doctors or general practitioners, public health officers, consultants, and whole-time teachers of medicine. Of 270 members of the Representative Body 19% were consultants; of the Council, which was elected by the members of the Representative Body themselves, 27% were consultants. The Past President, the Treasurer, the Immediate Past Chairman of the Representative Body, and the Deputy Chairman were all general practitioners. Thus it was ridiculous to say, as he had heard it said recently by a general practitioner, that the B.M.A. was a "consultants' ramp." He did not always see eye to eye with the decisions of the Association, but the interests of himself and his fellow practitioners, and indeed of the community, were safer in the hands of an organization representing the whole profession than in the hands of those who openly described themselves as representing only a sectional interest, and who restricted their membership to people belonging to that section. In conclusion Dr. Marshall said that the B.M.A. had gained much experience in carrying out negotiations in the past, and, difficult though they had been, future negotiations were likely to be even more difficult and perplexing. He then proposed the following resolution: "That in the opinion of this meeting the wishes of the medical profession in Northern Ireland can best be expressed and the interests of the profession can best be maintained by the B.M.A." This was seconded by Dr. Harold Gray and carried with 2 dissentients out of some 60 doctors who attended the meeting.

H.M. Forces Appointments

ARMY

Acting Col. W. J. Eastwood, R.A.M.C., Consultant, has been granted the local rank of Brig.

ROYAL ARMY MEDICAL CORPS

Major (War Subs. Lieut.-Col.) (Temp. Col.) T. L. Henderson to be Lieut.-Col.

TERRITORIAL ARMY, R.A.M.C.

War Subs. Major J. W. Leyack has relinquished his commission on account of ill-health and has been granted the honorary rank of Major.

War Subs. Capt. S. W. G. Hargrove has relinquished his commission on account of ill-health and has been granted the honorary rank of Capt.

Territorial Army Reserve of Officers: R.A.M.C.

Capt. T. Latham, from Cheshire Regt., to be Capt.

LAND FORCES: EMERGENCY COMMISSIONS

Royal Army Medical Corps

War Subs. Capt. J. P. S. Dunn has relinquished his commission and has been granted the honorary rank of Major.

War Subs. Capts. L. A. Willmott and J. J. Murray have relinquished their commissions on account of ill-health and have been granted the honorary rank of Capt.

Lieuts. P. L. F. Mortimer and H. W. Porter have relinquished their commissions on account of ill-health and have been granted the honorary rank of Lieut.

The surname of Lieut. J. J. McCann is as now described and not as stated in a *Supplement* to the *London Gazette* dated Feb. 26.

To be Lieuts.: A. P. Birks, W. G. Birrell, P. Buckley, F. C. Calvert, M. J. Colbourne, T. B. Dunn, J. J. Graham, P. J. Haga, K. N. Inman, J. E. Kerton, H. J. C. J. L'Etang, A. A. C. MacArthur, C. Moore, E. Morrison, R. Oddy, J. D. Paulett, J. Philip, J. Phillips, J. S. Pippard, L. Ruskin, B. Sheehan, C. P. Silver, J. M. Stewart, S. G. Tuffill, J. C. N. Westwood, F. W. C. Yardurnian, P. B. Adamson, M. Backwell, J. Barlow, G. E. Bent, B. Binnie, J. L. Boldero, F. Booth, H. B. Bouchier, J. McD. Brown, L. J. Bussell, D. S. Clark, G. E. Day, L. de Jongh, W. A. J. Donald, A. S. M. Douglas, E. N. Emmerson, M. Fogell, W. J. Fraser, J. W. Graham, A. T. Hendry, J. G. Jones, B. J. Kelleher, B. T. Kieft, D. R. McGaully, J. C. McGregor, A. J. McKendrick, A. A. Mackie, G. Millar, R. T. M. Paddicombe, W. M. Robertson, A. H. Smith, A. S. R. Stewart, G. R. Stoneham, O. C. Sugden, H. W. Thompson, J. J. W. O'H. Tobin, J. C. Watson, R. H. Wheeler, I. J. Williams, R. U. Whitney, G. Ashe, J. A. Bessett, H. I. C. Bowie, D. M. Brierley, R. Bryce-Smith, P. N. Cardew, R. D. Chalmers, W. H. Chase, J. D. Cooper, A. L. Ferguson, E. Grossman, J. D. Halford, B. Halpenny, G. E. Hicks, F. W. Jacobson, B. H. Jones, F. M. Lancaster, W. P. Lee, A. J. A. McCormick, J. R. McMichael, N. S. Malmison, V. D. R. Martin, A. C. Miller, I. Morris, W. L. Neustatter, A. Pearlman, D. S. Ridley, A. G. Scott, R. S. Starkey, J. M. Stuart, J. C. Swanson, C. J. O. Taylor, G. T. Wallace, H. Winch, H. N. Withan.

WOMEN'S FORCES

Employed with the R.A.M.C.

The following M.O.s have been granted commissions in the rank of Lieut.: Eileen M. Logan, Olwen B. Jones, Phyllis Morley, Dorothy P. Potter, Mary Pringle, Mary S. Smith.

ROYAL AIR FORCE

Squad. Ldr. (Temp.) R. S. B. McClean has been granted the rank of War Subs. Squad. Ldr.

Royal Air Force Volunteer Reserve

Flying Officers G. R. V. Coombs, R. R. Dickson, B. A. J. Arthure, D. J. N. Smith, J. Hood, F. A. Binks, J. Q. Craig, G. W. Senter, A. S. Majury, A. K. M. Macrae, and J. R. Hudson to be War Subs. Fl. Lieuts.

Flying Officer W. L. Milligan has relinquished his commission on account of ill-health and has retained his rank.

Flying Officer D. A. Davies has relinquished his commission on account of ill-health.

To be Flying Officers (Emergency): J. F. Swan, N. L. Birkett, J. S. Calnan, G. I. Davies, R. J. Evans, J. B. Foote, A. Inglis, D. G. Ismay, H. R. Kefford, J. C. Lloyd, H. E. Lockhart-Mummery, K. W. Lovel, E. A. Malkin, L. Mandel, R. M. Mason, G. J. Myers, C. R. Nash, P. N. Murphy, F. H. Stames, R. Stalker, J. O. Craig, C. N. D. Cruickshank, J. R. Fountain, A. G. Hardy, S. A. Holmested, T. F. McCarthy, E. S. Odbert, J. C. T. Reid, J. K. Russell, T. O. Scudamore, M. J. Smyth, E. B. Thornton, R. C. Rylance, B. G. C. Ackner, J. E. Adamson, I. J. Buchan, H. J. Fuller, P. R. Green, A. R. Harbinson, I. S. Kirkland, R. M. Laird, D. G. Simpson.

MEDICAL WAR RELIEF FUND

FORTY-FIFTH LIST

Amount previously acknowledged—£48,404 9s. 4d. and £100 3½% Conversion Stock and £40 3% Defence Bonds.

Individual Subscriptions

£422 7s. 5d. ($1,880.00).—Canadian Medical Association—per Dr. F. S. £45 1s. 1d.—Northern Rhodesia Branch—per Dr. Fisher (amount already sent, £35).

£24 11s.—Consett Division—per Dr. K. M. Macdonald (amount already sent, £22 1s.): Dr. W. Benson, £6 6s.; Dr. W. M. P. Henderson, £2 2s.; Dr. M. D. Mackenzie, £1 1s. (2nd donation); Dr. G. Ewen, £1 1s. (2nd donation); Dr. C. J. B. Fox, £2 1s. (2nd donation); Dr. M. M. Macintyre, £2 2s.; Dr. C. Fenwick, £2 11s. (2nd donation); Dr. G. M. Macintyre, £1 1s.; Dr. S. F. Breakey, £1 1s.; Dr. T. Lyons, £1 1s. (2nd donation); Dr. C. L. Laurent, £1 1s.; Dr. F. M. Fyfe, £1 1s. (2nd donation); Dr. K. M. Macdonald, £2 2s. (2nd donation).

£19 18s.—Doctors in the Isle of Man—per Dr. D. Pantin (amount already sent, £135 16s.).

£12 6s.—South-West Wales Division—per Dr. Rhys Paton Dr. J. Cook.

£10 10s.—Dr. T. Brice Poole, Hove (2nd donation)

£7 7s.—Dr. P. G. Levick, Bungay (3rd donation).

£5 5s.—Lieut.-Col. J. F. Ritchie, R.A.M.C. (ret.), Gateshead

£5.—Lieut.-Col. F. R. W. K. Allen, I.M.S.

£4 4s.—Dr. P. B. Spurgin, Great Yarmouth (3rd donation).

£3 3s.—Mr. P. Maynard, Fleet.

£2 2s.—Dr. G. L. Davies, Hove; Dr. A. Gilpin, London; Dr. D. E. J. Mitchell, Manchester (2nd donation); Dr. W. B. Moody, London (2nd donation); Dr. W. E. Smith, Glasgow (2nd donation).

£1 1s.—Dr. I. Preiskel, Oxford.

5s.—Dr. A. Cropley, London.

Local Medical and Panel Committees

£44 10s. 9d.—County of Ayr (9th donation).

£32 4s. 3d.—Midlothian (10th donation).

£20 10s. 6d.—Dumbarton County (9th donation).

£19 8s. 2d.—East Lothian (8th donation).

£5 5s.—Montgomeryshire (2nd donation).

Total—£49,097 16s. 6d. and £100 3½% Conversion Stock and £40 3% Defence Bonds.

Cheques, payable to the Medical War Relief Fund, should be sent to Dr. G. C. Anderson, Honorary Treasurer of the Fund, British Medical Association House, Tavistock Square, London, W.C.1.

DIARY OF SOCIETIES AND LECTURES

Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.—*Wed.*, 4 p.m. Mr. O. S. Tubbs: The Effect of Ligation on Infection of the Patent Ductus Arteriosus. *Fri.*, 4 p.m. Dr. G. Weddell: Cutaneous Innervation. Museum demonstrations: *Tues.* and *Thurs.*, 4 p.m. Prof. A. J. E. Cave: Osteology of the Shoulder Girdle and Upper Limb.

Royal Society of Medicine.—*Tues.*, 4 30 p.m. Section of Medicine. *Fri.*, 5 p.m. Section of Ophthalmology.

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue

BIRTHS

Bateman.—To Gwen, wife of Surgeon Lieut.-Cmdr. A. Daunt Bateman, O.B.E., R.N.V.R., on April 7, 1943, at Grosvenor Nursing Home, North Shields, a daughter.

Scott.—At Bournemouth, on April 16, 1943, to Rhoda, wife of Surgeon Lieut. Kenneth B. Scott, R.N.V.R., a son.

Correction

The reference to the Scottish amendment to clause (3) of the resolution before the Special Panel Conference (*Supplement*, April 10, p. 43) should read as follows: ". . . an amendment was carried recommending that it be remitted to Scotland to elect its own representatives, not to exceed six in number. With this amendment clause (3) was agreed to."

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL

LONDON SATURDAY MAY 1 1943

Correspondence

Policy: General and Medical

SIR,—In the present discussions regarding our future medical service attention is being focused on details of organization and administration, and very little is being said about policy. It would not be wise to assume from this that policy is a matter of small importance and so may be safely disregarded. Probably one would be nearer to reality in taking it as an indication that most of those engaged in the discussions are being kept in ignorance of the nature and source of the policy which is, in fact, being relentlessly pursued. It would seem, therefore, that some enlightenment on this subject is called for, and so an attempt will be made to provide it in as few words as possible.

Broadly speaking, there are only two possible policies for the world—freedom or domination. In a true democracy the source of policy is the will of the people (freedom). Under a dictator regime policy is imposed upon the mass of individuals from a centre of power (domination). Discerning lovers of freedom (for themselves and for others) rightly regard all centralizations of political power with suspicion, and those with some knowledge of present-day political developments are appalled at the rapidity with which centralization of this nature is being pushed forward. These persons realize that a centralized organization is a convenient instrument for the imposition of dictatorship, and that even democratic associations which have been brought into being by individuals for mutual help and protection may (and indeed in numerous cases have) become perverted and pressed into the service of domination of the individual.

A correspondent in the *Journal* wrote: "State medicine is the system in Hitlerite Germany, where it is used to support the Fascist theories of blood and the sterilization of political and racial 'undesirables.'" It is not likely that in this country a centrally controlled medical service (whether of salaried or extended panel type) could ever be used for these particular purposes, but it might easily become a useful instrument in the hands of those who are determined to turn England into a slave State. At any rate, Assumption B of the Beveridge report (now officially accepted by the B.M.A.) should put us on our guard. I, for one, cannot believe that it has been inspired by a genuine democratic policy. The people of this country simply do not believe that man's chief end is work. The end-point of a comprehensive health and rehabilitation service is not "restoration of capacity for work." It *may* be restoration of capacity for "life, liberty, and the pursuit of happiness."

The latent policy of the Divisions of the B.M.A. is freedom for doctors as individuals. This policy must be made effective throughout the B.M.A. from the circumference to the central executive. A very hopeful sign is that medical policy groups have begun to spring up in different parts of the country.—I am, etc.,

Bexley. E. U. MACWILLIAM.

State Medical Service

SIR,—A State Medical Service may appeal to many of the younger members of the profession, but whether it would be an advantage to the doctors or the public is open to question. There is not much fault to be found with the present state of the medical services in this country. The highest skill in medicine and surgery is available for every individual—male or female—however poor his or her circumstances may be, thanks to the voluntary hospitals. One would think it would be time enough to discuss the question of a State Medical Service not sooner than six months or a year after peace is declared, so as to give sufficient time to the practitioners at present serving with the Forces to get back to their normal civil work. Until such a time arrives it appears to me to be taking a mean advantage of these men even to discuss the question of a State Medical Service.

In the many articles and letters appearing in the *Journal* recently there is little mention made of how medical practitioners are to be remunerated under a State Medical Service, and at what age superannuation would take place, and in the event of earlier death what provision would be available for their dependants. These are vital considerations for the general medical practitioner.

There are very many general practitioners at home and serving with the armed Forces who have sunk money, often borrowed, to purchase practices or partnerships. How does the Government intend to recoup these men for the loss of their money and practices? Before the war the goodwill of both panel and private practices could be sold at one or two years' purchase, or even more, but if a State Medical Service came into force the goodwill of these practices would be worthless. In many cases when a practitioner died the saleable value of the goodwill of his practice was often the chief means of livelihood available for his widow or dependants.

The Beveridge scheme holds many attractions for the working man, and we would all like to see social security for everyone, and the gaunt spectre of poverty removed from every home. The Prime Minister, however, does not see his way to commit the Government to all the scheme entails, and I ask, Why should the profession be committed to the medical side of the scheme until such time as the Government sees its way to implement the scheme *in toto*?

The lot of the general practitioner is not an enviable one. Day and night in fair and foul weather, and at every season of the year, he is at the beck and call of his patients, and the strenuous life he leads is not conducive to longevity. He is often cut off before he has had time to make provision for his wife or dependants. Knowing his patients' financial circumstances he often has to do a lot of his work gratuitously. If compelled, therefore, to serve under any Government scheme he is entitled to a fair and honourable deal.

I have been nearly 50 years in general practice, but have never served under the National Health Insurance Acts.—I am, etc.,

DUNCAN MACDONALD, M D., C.M.
Oban, Argyll.

Materialism in Planning

SIR,—Dr. Terence Turner (*Supplement*, April 10, p. 48) in his comments on my letter points out that Mr. Churchill declared himself as being whole-heartedly in favour of compulsory national insurance. It cannot be denied, however, that he also said, "Let private enterprise and State enterprise combine to pull along the national wagon." I am sure Mr. Churchill would not wish to single out the medical profession especially and alone for State enterprise. I should be very grateful if my solicitor and my chartered accountant would deal with my affairs on comprehensive terms applicable to the whole nation.

I am pleased that Dr. Turner has not made any adverse comments on my previous letter of March 27, and I think this shows the general swing of the medical profession from its previous totally idealistic view to a more materialistic one of our grave situation. I am sure that everyone will agree that the very large section of the public for whom a comprehensive medical service is particularly designed has shown a very materialistic attitude during the past four years.

Dr. Turner, as chairman of the Guildford Study Group, has called attention to a letter from Mr. Steele, the secretary of the Study Group, in your issue of April 3, in which he recommends other Study Groups to follow the lead of Guildford and invite their local M.P.s to hear their views. I think it would be better if the local Divisions would invite their M.P.s to their Division meetings rather than to the smaller Study Group meetings, as I am quite sure that if Sir John Jarvis had come to the Guildford Division meeting in March he would have formed quite different impressions from those he took away from his meeting with the Study Group. I cannot be dogmatic on this point as no mention of this meeting of the Guildford Study Group was made beforehand, and I have never seen any report of its proceedings.

In my opinion there have already been far too many secret sessions and far too much of the "run away and play, little doctor" about this subject which concerns us all. I cannot see this great need for secrecy, for surely there is no enemy greedy for information. It cannot have been forgotten that the last great step in the socialization of medicine—that is to say, the raising of the income limit for insured persons to £420 a year without any increase in the capitation fee—became a *fait accompli* while we thought it was still under discussion. The fact was announced casually over the wireless owing to an oversight on the part of the Ministry. It was a succession of such *faits accomplis* and such oversights on the continent of Europe which led up to Munich and after.—I am, etc.,

Camberley LESLIE HARTLEY.

CHILD WELFARE IN THE UNITED STATES

At a recent meeting of the Maternity and Child Welfare Group of the Society of Medical Officers of Health, Dr. Catherine Morris Jones presiding, Major Becker of the United States Army Medical Corps, who was until recently paediatric consultant to the Kellog Foundation and consultant to the Michigan State Department of Health, spoke on child welfare in the United States. He drew attention to the impracticability of applying a scheme of medical or social welfare to the whole of the United States, owing to the wide variations in population, conditions of living, and environment in different parts of the country. The agencies for maternal and child welfare were Government-controlled (Federal, State, city, or county Government) and private agencies—i.e., mainly philanthropic foundations and trusts or voluntary societies dealing with a particular branch of child welfare. After the last war, under pressure of public opinion arising out of the reports of the children's committee appointed by the Federal Government, co-ordinated Government schemes were started, the Federal Children's Bureau was organized, and a committee on the cost of medical care was appointed, also by the Federal Government. This last committee found that adequate curative and preventive medical care was then beyond the reach of a large proportion of the middle and lower classes. Federal Government aid was directed primarily to education and to fact-finding activities It was not executive in function and did not directly subsidize treatment or relief. Grants were made to a State under conditions and subject to agreed expenditure by the State also, which might in turn distribute financial aid and allocate responsibility to constituent counties. The privately controlled agencies for health and welfare numbered thousands. Many were in touch with Government Departments and might be used by them for specific purposes.

Describing the work of the Kellog Foundation, Major Becker said that its resources were first directed towards improving the health of the children of the State of Michigan by creating or financing clinics, hospitals, etc The absence, however, of any appreciable permanent effect on succeeding generations led to a shifting of the emphasis on to education, and especially the education of doctors and of the public through schools, the clergy, and the newspapers. For doctors the Foundation arranged meetings and postgraduate courses in paediatrics and obstetrics, and supplied the services of consultant paediatricians, whose work was deliberately educative as well as clinical.

H.M. Forces Appointments

ROYAL NAVY

Surg. Capt M. S. Moore has been placed on the Retired List

ROYAL NAVAL VOLUNTEER RESERVE

R. G. Henderson to be Temp Surg Capt

Prob Temp. Surg Lieuts. P. A. Adam, P B. Maxted, T. A. M Johns, S. N Cole, R. H Alexander, and H A. Fleming to be Temp Surg. Lieuts

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MAY 8 1943

SHEFFIELD DISCUSSION GROUP

VIEWS OF HOSPITAL ASSISTANTS AND RESIDENTS

The honorary secretary of the Sheffield Hospitals Assistants and Residents Medical Planning Discussion Group has sent the following report of its procedure and conclusions for publication.

The group was formed in March, 1942, for the purpose of providing the more recently qualified members of the medical profession in Sheffield with opportunities for discussing medical planning and expressing their views on future medical organization. It was felt that the younger men and women who had qualified within the last ten years and many of whom would shortly join the Forces had too little representation on the medical planning bodies already in existence.

A series of discussion meetings was held, and at the end of these a questionary was sent out to all the assistants and residents in the Sheffield hospitals, voluntary and municipal. This was designed to elicit the opinion of the group on the issues which had been raised in discussion. Twenty-three questionaries (about a third of those sent out) were completed and returned. Of the twenty-three who filled in the questionaries, eighteen were men; five of these are now serving in the Forces. None has been qualified more than ten years and the average time since qualification is four years. The group includes graduates of seven British universities.

The conclusions contained in this report represent the opinion of three-quarters or more of those who completed the questionary. Where a majority but less than three-quarters were in agreement this is stated as a majority opinion.

Conclusions

The preventive and curative medical services should be integrated into one health service and should not be separately directed. To this end the following criticisms and proposals were made.

1. Hospital Services

Administration.—There is lack of co-ordination between voluntary hospitals, municipal hospitals, and nursing homes. Municipal hospitals are at present directed by a medical superintendent, whose responsibilities are so widespread that he cannot do justice to both administrative and medical duties. Hospitals should be co-ordinated and directed by regional councils, to be responsible to a National Medical Corporation. This corporation might be constructed on similar lines to the B.B.C., and 50% of its Governors should be medical men. Hospitals should be co-ordinated within regions larger than the existing local government areas, and in each region a teaching hospital should act as the key hospital. Each hospital should be administered by a medical committee and a lay committee. The medical committee, consisting of the senior medical staff, would be responsible for the appointment of medical staff and for the direction of all medical matters. The lay committee, composed of representatives of local organizations, would, in association with representatives of the medical committee, direct the general and financial administration of the hospital.

Staffing.—All consultants should be associated with a teaching hospital and should receive a salary for their hospital work. Each consultant should possess a higher qualification in his particular specialty, and should have spent a preliminary period variously estimated at from 2 to 12 years in the practice of the specialty. It was recommended that he should have devoted a period of at least one year to study abroad. The majority were opposed to the retention of private consultant practice.

Finance.—The methods at present employed to finance voluntary hospitals were condemned. The majority favoured financial support from a compulsory health insurance scheme. Others suggested financial administration by the Exchequer from a fund derived directly from income tax.

2. General Practice

General practitioners often have too many patients and too much clerical work. With the surgery in the home, the doctor's home life is disturbed, particularly by having to stand by for telephone calls. General practitioners become professionally isolated and find it difficult to attend study courses and visit other centres. The buying and selling of practices was considered undesirable, and difficulties often arose in the assessment of fees. Much interesting work was being taken over by the public health departments—e.g., ante- and post-natal work, infant and school welfare. This resulted in a still greater lack of co-operation between general practitioners and public health departments.

The group thought that general practice should be carried out from health centres, each of which should cover a population of approximately 15,000 and be staffed by about ten doctors working in close collaboration, thus providing a rota for night calls and opportunities for holidays and visits to other medical centres. The health centres should be co-ordinated with the hospitals in the regionalization scheme, thus eliminating unskilled specialization in group practices and small town hospitals. Public health personnel and services should be unified with general practitioners in health centres, and the centre doctor encouraged to do some of the medical work now taken over by the public health departments, provided he had undertaken special training. Doctors should be appointed to the centres by the regional medical authority on the basis of ability, and paid a basic salary in addition to a capitation fee for each patient attracted up to a maximum of 2,000.

A clerical staff would deal with all financial matters and be responsible for a well-kept system of records, filed and analysed, thus facilitating the work of locumtenents and stimulating interest in investigations and follow-up inquiries. The principle of free choice of doctor should be maintained.

3. Medical Education

Selection of Students.—This should depend upon the student's character and motives for entering the profession. Inability to pay the fees should not debar an otherwise suitable candidate. The majority thought that the number of doctors needed by the population should also be a controlling factor.

Qualifications.—A more uniform qualification is desirable, and a resident hospital appointment following qualification should be required before admission to the *Register*.

Teaching and Teachers.—In the appointment of medical teachers more consideration should be paid to the possession by the applicant of the ability to teach. Teachers should be allowed to do research, but the majority thought that they should not engage in private practice or accept public appointments. It was thought that the general practitioner should play some part in the teaching of students.

4. Medical Research

More facilities should be available in hospitals for the prosecution of research. Research departments should be created in all teaching hospitals, with a paid director, whose duties would include the initiation and co-ordination of research within the hospital.

5. General Questions

Payment of the Doctor.—The group considered that the doctor should not be paid directly by the patient or through doctors' clubs, but should be paid either by means of an insurance scheme open to the whole population or by the State on a salary basis with pension, or by a combination of these two methods.

Health and Environment.—The medical profession should have more power to ensure satisfactory health standards of housing, water supplies, nutrition, and other environmental factors affecting health.

There was a pleasing interlude at the annual meeting of practitioners of the North Glamorgan and Brecknock Division of the B.M.A. on April 18 at Pontypridd. The honorary secretary of the Local Medical War Committee, Dr. R. Melville Hiley, was presented with a cheque by Dr. Gwilym Pierce, chairman of the Division, on behalf of the profession for his valuable services over many years. Drs. Watson (Talgarth) and Melbourne Thomas spoke of Dr. Hiley's services. Dr. Hiley has been honorary secretary of the South Wales and Monmouthshire Branch, a chairman of the Division, and is honorary secretary of the Division in addition to his onerous duties as honorary secretary of the Local Medical War Committee.

CONSULTANTS AND SPECIALISTS GROUP: REGIONAL MEETINGS

Regional meetings are being arranged throughout the country under the auspices of the Consultants and Specialists Group of the B.M.A. These meetings will afford opportunities for discussion of the proposals relating to the future of consultant and specialist practice upon which consultants and specialists may desire to express an opinion to the Representative Committee appointed to enter into discussions with the Ministry of Health. In view of the Government's proposals arising out of the Beveridge report, consultants and specialists who are not members of the Group are invited to attend these meetings and to participate in the discussions. Membership of the Group is, however, restricted to those members of the Association who sign a declaration that they are not engaged in general practice in any form but practise exclusively as consultants or specialists. Forms of application for membership of the Group may be obtained from the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1. Details of the regional meetings arranged to date are given below:

Region 11: London (the geographical counties of Essex, Hertfordshire, London, and Middlesex).—Wednesday, May 19, at 5 p.m. at B.M.A. House, Tavistock Square, London, W.C.1. The discussion will be opened by the following speakers, Mr. H. S. Souttar presiding: Dr. W. Russell Brain, Dr. Geoffrey Bourne, Mr. A. Dickson Wright, Mr. Donald Barlow, and Dr. G. C. Anderson.

Region 2 (Manchester and that part of Lancashire not within the Liverpool Region).—Thursday, May 20, at 5 p.m. in the Lay Board Room, Manchester Royal Infirmary. The discussion will be opened by Prof. Harry Platt.

Region 5 (Sheffield, Rotherham, Doncaster, and the county of Rutland).—Thursday, May 27, at 3 p.m. at the Royal Infirmary, Sheffield. The discussion will be opened by Mr. R. St. L. Brockman.

Region 6 (the geographical counties of Derby, Nottingham, and Lincoln).—Wednesday, May 19, at 2.30 p.m. at 64, St. James's Street, Nottingham. The discussion will be opened by Mr. S. Alan S. Malkin.

Region 7 (Birmingham and the geographical counties of Stafford, Salop, Hereford, Worcester, Warwick, Leicester, and Northampton).—Saturday, May 22, at 2 p.m. at the Nurses Home, Queen Elizabeth Hospital, Birmingham. The discussion will be opened by Prof. Philip C. Cloake.

Region 9 (the geographical counties of Berkshire, Buckinghamshire, and Oxford).—Wednesday, June 2, at 2.30 p.m. at the Nuffield Institute of Medical Research, Woodstock Road, Oxford. The discussion will be opened by Dr. A. M. Cooke.

Region 12 (the geographical counties of Kent, Surrey, and Sussex).—Saturday, May 15, at 3.30 p.m. at the Royal Pavilion, Brighton. The discussion will be opened by Mr. H. J. McCurrich.

Region 13 (the geographical county of Hampshire and the Isle of Wight).—Thursday, May 13, at 3 p.m. at the Royal South Hants and Southampton Hospital, Fenshaw Street, Southampton. The discussion will be opened by Dr. R. H. Balfour Barrow.

Region 14 (the geographical counties of Devon and Cornwall).—Wednesday, May 19, at 2.30 p.m. at the Prince of Wales Hospital, Greenbank Road, Plymouth. The discussion will be opened by Dr. T. H. G. Shore.

Region 15 (Wales and Monmouthshire).—Thursday, May 20, at 3 p.m. at the Cardiff Royal Infirmary. The discussion will be opened by Mr. David Ioan-Jones.

Hypodermic needles and syringes for the self-administration of adrenaline are now available as part of medical benefit under the N.H.I. Acts.

Correspondence

Basic Principles

SIR,—The West Norfolk Division of the B.M.A. has noted the publicly expressed intention of the political parties to introduce a national health insurance scheme for the population as a whole. The members of this Division have met many times and have sent to the Medical Secretary of the B.M.A. suggestions for safeguarding the interests of doctors. We now tabulate various principles which we consider should be insisted upon by any committee representing the medical profession in discussions or negotiations.

1. Full compensation for the loss of capital assets, practice, premises, and equipment, and also for loss of income that may arise from any scheme adopted.
2. Equal rights with other citizens in the matter of weekly duty hours and yearly holidays.
3. The terms of remuneration discussed shall be deemed to apply to the national working week. Those who at first of necessity will work longer hours shall have special additional overtime remuneration.
4. There should be comprehensive safeguards against the possibility of our wives and children becoming unpaid assistants and domestic servants in the scheme.
5. Freedom to treat our patients according to our knowledge and conscience and not according to the rules laid down by some administrative body.
6. If, by restricting the number of patients or by any other means, our maximum income is limited, then a minimum net income must be guaranteed.
7. No impediments or limitations must be placed on a doctor continuing to practise after he has contracted out of the scheme.
8. Complete freedom of the doctor in his off-duty time to do medical or other work as he wishes.
9. Any controlling body or committee shall include a percentage of doctors doing clinical medicine as in the panel committees.

We consider that these principles should apply to any generalized national medical service (whether 85% or 100% of the population are included) no matter if the remuneration is by salary, session, or capitation fee. We are anxious to know the opinions of other Divisions on these or other general principles (details can be discussed later) either through your columns or by letter direct to us.—I am, etc.,

J. LEWIN,
Hon Secretary, West Norfolk Division.
Gaywood Hall, King's Lynn.

A Disclaimer

SIR,—An anonymous communication dealing with a speech of mine upon co-operation between the M.P.U. and the B.M.A. has recently been widely distributed. It emphasizes certain aspects of disunion between those two bodies which I was anxious to avoid, and I trust you will allow me space to state that I have no responsibility whatever for the document in question.—I am, etc.,

Sevenoaks. GORDON WARD.

Doctors as Civil Servants

Dr. B. H. SHAW (St. Mawes) writes: From time to time it has been suggested that the medical profession should have greater representation in Parliament. It is pertinent to ask how, if the profession is to be converted into a Civil Service, can this be effected in such an event, or even the appointment of a medical man to a Commission of the Peace?

POSTGRADUATE NEWS

The Fellowship of Medicine announces: (1) M R.C.P. course in chest diseases at Brompton Hospital, Tues and Thurs., 4.30 p.m., May 18 to June 10. (2) M R.C.P. course in chest diseases at London Chest Hospital Victoria Park, 2.30 p.m., on Fri., May 28 and June 4, and Tues., June 1 and 8 (3) Clinical surgery demonstrations at London Homoeopathic Hospital, every Wed. afternoon during May and June Further details of these courses can be had from Fellowship of Medicine, 1, Wimpole Street, W 1.

MID-CHESHIRE DIVISION.—At Altrincham General Hospital, Sun, May 9, Annual meeting, preceded by meeting of all practitioners in area of Division for election of Local Medical War Committee, 1943-4.

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTHS

KAHAN—On April 21, 1943, at the Southern Hospital, Dartford, Kent, to Dr. Nest Kahan (*née* Thomas), wife of Dr. Alexander Kahan, a son.

McKEE—On April 25, at the Royal Infirmary, Sunderland, to Dr. and Mrs John McKee of Harton, South Shields, a daughter.

MARRIAGE

LANGLEY—PORTER.—On April 29, at Buxworth Parish Church, George Johnson Langley, M.D., F.R C.P., of West Acre, Oldfield Lane, Altrincham, to Elsie Porter, M D., daughter of Lady Porter, 9, Lyme Park, Chinley.

The Glasgow Panel Committee has passed a resolution unanimously declaring that "it would deprecate the general practice side of any National Medical Service being put under the administrative control of the present local authorities or any future groupings of the same. It would favour the administrative control of general medical practice being regional, or, alternatively, the control being the direct responsibility of *ad hoc* bodies."

BRITISH MEDICAL JOURNAL
LONDON SATURDAY MAY 15 1943

Correspondence

Why Reorganize ?

Sir,—Like many others, when the Beveridge report came out with its prepublication boosting *à la* Goebbels, its B.B.C. blessing and so forth, I thought it was, basically, a good and desirable measure, but having read the letter of Dr. Leach (*Supplement*, April 3), I have been communing with myself and asking myself if this report is really the only panacea for all the ills and shortcomings of the medical profession. It is, I think, tacitly admitted that the medical profession is far from perfect. I should, indeed, be deeply indebted if you could inform me of any section of the community which is perfect. They all, I take it, in our present system of civilization suffer from greater or lesser degrees of imperfection, but, as Dr. Leach implies, the medical profession stands out above all others in the eyes of the reformers or regimentators as the one deserving of their united frontal assault. Apparently they consider that this great and noble profession is a perfect sitting target which will immediately capitulate at their first broadside. The public, generally, considers that the medical profession is the strongest trade union in Britain to-day; indeed, many of my patients and friends have frequently so described it to me. No amount of argument can alter this conviction on their part. The reformers know this.

One has heard nothing, as yet, of any scheme which is going to regiment the herbalists, the naturopaths, the osteopaths, the physiotherapists, and those super-scientists, the manipulators of the black boxes. They, presumably, with their intensive, all-embracing correspondence courses to gain new graduates, are to be allowed to retain their freedom of action. Of course they will still not be allowed to issue death certificates or prescribe dangerous drugs, or will they? Judging from the support they have already received from certain of our reactionary Members of Parliament one can expect almost anything. We, however, having spent many years in the study of our profession and having, in most cases, laid out a considerable amount of money on the purchase of a practice, are now to be put on one common level and treated as the office boys of the great Ministry of Health, or Ministry of Positive Health, as it may well be renamed.

We are, if our propaganda is to be believed, fighting this war for the preservation of all that democracy means. Democracy, surely, does not mean that the State rules the individual, but rather that the individuals rule the State. We are fighting against all the evils of Nazism and Fascism, and the greatest evil of these two systems of government, as I see it, is that each puts the State first and foremost and the individual is only considered as a means to the continuance of the paramount position of the State. Yet our so-called planners are evidently striving to bring Britain into line with the Reich and Italy. If they have their way this great country of ours will be in no way different from the Axis countries. Indeed, it will be a case of totalitarianism excelled.

If we believe that the principles for which we entered this war are worth fighting for it is high time we asserted ourselves. Let us unite and tell the planners and the Ministry of Health that we will not submit to their demands. We know, and the general public knows, that on the whole we are doing a good job of work. We know, as Dr. Leach has said, that the availability of service is at hand for rich and poor alike. That certain matters can be improved is denied by nobody, but it does not need the regimentation of the whole medical profession to get the needed improvements. The time is short. The Minister of Health has said that plans for a State Medical Service are well under way, and we can believe him: he means what he says. Let us, therefore, get together and show a united front for once. Let us, for the first time, be a real trade union, and fight to preserve our freedom. President Roosevelt has said that we are fighting for four freedoms: freedom from want, freedom from fear, freedom of speech, and freedom of religion. And an ex-President, Herbert Hoover, has added a fifth—freedom of economic enterprise. The G.P. who does his work badly loses his practice. The G.P. who does his work properly keeps his practice and increases it—all by his own effort and enterprise. Shall we stand quietly by and allow the rewards of hard work and enterprise to be filched from us without a struggle? Let us rally to the old slogan of the Jacobins—"Liberté ou la mort"—rather than adopt the defeatist slogan of "Esclavage plutôt que la mort." Only thus may we hope to thwart the evil designs of the regimentators.—I am, etc.,

William Mottershead.

Little Lever, Nr. Bolton.

The Rural Doctor

Sir,—Some twenty-odd years ago the cause of the rural practitioner was championed with great effect by Dr. Williams Freeman of Hants, whom many may remember. It is perhaps a good omen that Dr. E. R. Williams, a truly rural doctor, has been added to the Representative Committee appointed to meet the Minister of Health. Certainly the needs and desires of this important section of the profession must have careful consideration in the "new deal," and I suggest that the Rural Practitioners' Subcommittee of the Insurance Acts Committee of the B.M.A. is well qualified to ensure that this is done. Doctors working in rural areas should make contact with their Panel Committees, so that their views may be brought to the notice of the authorities. As a basis for discussion I submit the following suggestions.

For obvious reasons the countryside needs a capable, self-reliant doctor, well equipped in all branches of general practice, and no whit inferior to his urban colleague. In the rural areas there can be little free choice of doctor or of patient. His practice must stand on its own financial feet and ought not to depend on a subsidy from private means or pension. The rural areas have a fairly stable population, and doctors should be encouraged to settle there early in their professional career and to stay there. A rural doctor has several handicaps. Under present circumstances he cannot make a fair income. He cannot sell so much of his professional time as his town colleague, as so much of it is spent travelling. Facilities for his children's education are more expensive and difficult. Association with his colleagues is not easy.

The future plan must provide him with an income equal to that of an urban practitioner. The present unsatisfactory method of supplementing his income from the reserved portion of the Mileage Fund by application to the Panel Committee must be abolished. The mileage fee in rural areas ought to take into account payment for time spent in travelling as well as the actual cost of getting about. He must have a postgraduate course provided every few years, and also an annual holiday for which a locumtenent should be provided and paid. He needs a dispenser-bookkeeper so that all his time may be devoted to professional work, and to help him keep branch surgeries in different parts of his area. This help will be the equivalent of the health centre in the towns.

If the countryside is to become more popular and important in the future its medical needs must be satisfied with service as good as that in the towns.—I am, etc.,

Weymouth. J. A. Pridham.

A Call for Leadership

Sir,—Many of us have left behind a dull resignation to the medical planning of the Beveridge report, a resignation forced upon us by the realization that the medical profession, by its organization to discuss details and conditions of service, had accepted or at least were prepared to tolerate the scheme itself. What we need now is a leader, a Churchill. Letters such as the one from Dr. Lindsey Batten (*Journal*, March 13, p. 328) give real encouragement. Let those of us who share his opinions gather together under the same banner. Will a leader come forward?

It is to be noted that: (*a*) Our opposition is not directed against the Beveridge plan as a whole but merely to the medical scheme contained therein. (*b*) Suggested changes come from politicians and not as the result of any demand from the general public or from the body of our profession. (*c*) The present system is not perfect and cannot be static. Nevertheless its gaps are few, and these can be filled by simple extension of the N.H.I. scheme.

To take two instances: (1) The patient who, while too ill to attend hospital, is considered by his G.P. to need the advice of a consultant. It is believed that a sufficient number of consultants would serve on a panel for this purpose in each area under conditions agreed upon between representatives of themselves and of the Ministry of Health. (2) The patient who, not being an insured person and being unable to maintain the small regular subscription towards medical service under the P.M.S., is not agreeable to asking for the services of the P.A. ("parish") doctor. These patients could be treated as insured persons, and temporary cards, renewable at intervals, could be issued to them.

Any extra cost involved would be a very small proportion of the sum necessary to extend the present service to that of the Beveridge scheme, and although extra work would fall on the staff of insurance committees no fresh machinery of organization would be entailed. What would be our lot under a Fascist regime? Surely a regimentation of the Beveridge type. I am not deterred from this view by the fact that the Government has promised us that in the preliminary discussions our voice may be *heard* (without prejudice to any *decision* subsequently taken by Parliament!).

If we are to be sheep, let us follow a good-shepherd rather than be driven by a political sheep-dog. Who will come forward to lead us?—I am, etc.,

Leicester L. Duncan Porteous.

MEDICAL WAR RELIEF FUND

FORTY-SIXTH LIST

Amount previously acknowledged—£49,097 16s 6d and £100 3½% Conversion Stock and £40 3% Defence Bonds.

Individual Subscriptions

£62 11s. ($279.60).—Canadian Medical Association—per Dr F. S. Patch (amount already sent £1,910): Oxford County Medical Association, Ontario, $99.60; Prince Albert District Medical Society, Saskatchewan, $60 00; individual subscriptions from Saskatchewan, $120 00.

£7.—Birmingham General Medical Practitioners' Union—per Dr M. G. Sheldon (amount already sent £49 7s) - Drs Morison and Watt, £3 (2nd donation); Dr J. Radnor, £1; Dr. J. A. Brown, £1 (2nd donation); Dr. N. F. Haslam, £1 (2nd donation); Dr. M. G. Sheldon, £1 (4th donation)

£1 1s.—Major J. Duncan White, R.A.M.C.

£1.—Dr G. D. Denlow, Kingston (3rd donation).

Local Medical and Panel Committees

£280.—Surrey (6th donation)

£80.—Stirling County (3rd donation).

£42 17s. 6d.—Newcastle-upon-Tyne (7th donation).

Total—£49,577 11s and £100 3½% Conversion Stock and £40 3% Defence Bonds

Cheques, payable to the Medical War Relief Fund, should be sent to Dr. G. C. Anderson, Honorary Treasurer of the Fund, British Medical Association House, Tavistock Square, London, W.C.1

The Ministry of Health has informed insurance committees that medicated (lethane) hair oil may properly be prescribed for insured persons as part of medical benefit. Extensive trials have now proved that it is thoroughly efficient and safe when the official directions given in the *National War Formulary* and on the label are followed.

CONSULTANTS AND SPECIALISTS GROUP: REGIONAL MEETINGS

In the *Supplement* last week (p. 58) attention was drawn to the regional meetings being arranged throughout the country under the auspices of the Consultants and Specialists Group of the B.M.A. Details of further regional meetings are now available and particulars are given below:

Region 1 (the geographical counties of Northumberland, Durham, Westmorland, and Cumberland).—Thursday, May 20, at 6 p.m., at the Royal Victoria Infirmary, Newcastle-upon-Tyne. The discussion will be opened by Brig. A. Hedley Whyte.

Region 3 (Liverpool, Merseyside, and Cheshire).—Wednesday, May 26, at 5 p.m., at the Liverpool Medical Institution. The discussion will be opened by Mr. F. J. Strong Heaney.

Region 8 (the geographical counties of Huntingdon, Bedford, Cambridge, Norfolk, and Suffolk; Soke of Peterborough and Isle of Ely).—Thursday, May 20, at 2 p.m., at Addenbrooke's Hospital, Cambridge. The discussion will be opened by Mr. A. J. Blaxland.

H.M. Forces Appointments

MARRIAGE

Essex-Lopresti—Harrop.—On May 1, 1943, at Brompton Oratory, Peter Essex-Lopresti, F.R.C.S.Ed., D.A.Eng., to Mary Muriel Harrop, M.B., B.S.Lond.

DEATHS

Craighead.—During March, 1943, at sea, through enemy action, Alexander Clifton Craighead, Lieut.-Colonel, Indian Medical Service, beloved husband of Ellie Campbell McKenzie, 32, Park Road, Dundee, in his 53rd year. (Indian and Australian papers please copy.)

Cunningham.—On May 7, 1943, Richard Graham, M.B., Ch.B.Ed., aged 64, dearly loved husband of Jean Hunter Cunningham of The Firs, Bamburgh, late Sunderland.

A suggestion in a recent issue of the *Yorkshire Post* that medical men and women employed by local authorities should, where possible, help overworked G.P.s has provoked a reminder from the West Riding that this has been the practice there for nearly three years. School, tuberculosis, and maternity and child welfare medical officers of the West Riding County Council have been giving their help in hospitals and private practice wherever urgent need for assistance arose.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MAY 22 1943

THE GOVERNMENT'S PROPOSALS

MASS MEETING OF METROPOLITAN COUNTIES BRANCH

The Great Hall of the B.M.A. House in Tavistock Square was entirely filled on Sunday afternoon, May 16, for a special meeting of members of the Metropolitan Counties Branch to discuss the tentative proposals of the Government for implementing Assumption B of the Beveridge report. Sir CRISP ENGLISH (President of the Branch) was in the chair, supported by Mr. H. S. SOUTTAR (chairman of the Representative Committee), and the meeting was addressed by Dr. CHARLES HILL (Deputy Secretary of the Association). The address was received with unusual acclamation, and more than one speaker subsequently described it as the most cogent he had ever heard in a medico-political assembly.

Dr. Hill began by saying that non-committal discussions were now taking place between officials of the Ministry and representatives of the medical profession. Before long a White Paper embodying the Government's tentative conclusions would be published, and in the light of its consideration by the public and by interested bodies the Government would proceed with legislative preparation for a comprehensive medical service scheme at or soon after the end of the war. These confidential discussions had received attention in the Press, and what was in the Government's mind had been revealed in the *Daily Express* and in the *Evening Standard*; in the circumstances he felt compelled to tell the meeting frankly the substance of the exchanges. What the Ministry of Health had put forward were so far non-committal suggestions, but they represented the workings of the Ministerial mind.

The Administrative Set-up

On the "dusty subject" of administration the Ministry rejected the conception of a corporate body, preferring departmental control under the political leadership of the Minister. At the centre it was proposed to elaborate the machinery for securing professional advice by setting up a Medical Service Council, three-fourths of its members to be nominated by the profession and the remainder by the Minister. This body would have a statutory basis and the right to issue its own reports. In addition there would be a Central Medical Board with executive authority in certain domestic matters. Locally there would be a grouping of most local authorities for health purposes by means of joint boards. The Minister's mind was not closed to medical membership of these boards, but such membership would probably be small.

The Minister proposed that general practice, at least in areas of considerable population, should be based on health centres, where—although this was rather vague—such local authority clinical work as normally came within general practice would also be done. Believing that health centres should be the basis of the service, and that competition between doctors for patients under the roof of the centre was undesirable, the Minister proposed that, in the main, general practice should be conducted on a salaried basis. Those now in general practice would enter the service, if they chose, either as whole-time or part-time officers; in the latter case they would engage in private practice among that section of the community which, although entitled to State services at the health centre, preferred to consult a doctor privately. New entrants would have no choice except between whole-time salaried service and staying out. The proposals included compensation for loss of practice. He had not intended to mention the salary scale, but it had been published in the *Evening Standard*: after an initial period as house officer, an entrant into the service would have a salary of £400 a year for three years; thereafter he would normally expect to become a principal at a salary of £650, rising by annual increments of £30 over approximately 18 years to £1,200. Expenses, including travel, would be paid in addition. On completing his house appointments the future practitioner would make application to enter the service, and one of the functions of the Central Medical Board would be to prepare a roll of members. Having got over this hurdle, he would, with the help of the board, seek appointment by a health authority, with which his contract would be made, and he would be subject to three months' notice.

The proposals for the consultants were more vague. The consultants would be centred on a hospital, but their appointment, based on nationally accepted criteria, would be by the local authority and would be whole-time or part-time "according to circumstances."

Why the Hurry?

Having sketched the proposals, Dr. Hill proceeded to make some comment. First of all, why the hurry? Why was the Government pressing forward with such energy one section of the Beveridge proposals? It might be that it was anxious to do something, and found a body of 50,000 men and women comparatively easy to handle; but in his view the fact was that the Government had decided that before the major structure of the security scheme could be elaborated it was necessary to control the medical profession so that certification could be controlled. Remarks in the Beveridge report and in Ministerial statements therewith suggested that interpretation. Medical certification would be responsible for the major outgoings of the proposed security fund, and as these outgoings were to be increased it was necessary to establish a stricter control over certification. "Our answer is obvious. The doctor's job is to decide whether a man is fit for work, no matter whether the cash value of his certificate is five or fifty shillings a week" (Applause.)

As for the "comprehensiveness" of the scheme, it was not "comprehensive" so far as Government Departments were concerned. There was no proposal by the Government to put its own house in order and bring in all the scattered medical services in its Departments. Local authority government was embedded in the social fabric. But was this a genuine proposal to abolish smaller authorities and to concentrate health functions in bodies of sufficient strength and financial capacity to discharge them? The fact was that rural and urban district councils were still to be left with environmental health functions; that education authorities would remain responsible for the school medical service. Again, the mental health services were to be left as a separate entity, simply because mental health legislation was in a terrible mess, which would take time to clear up. From the Government's point of view there was no time for this.

"A Branch of Local Government Service"

As for the health centre, it was agreed that group practice would produce a better service; but before a single health centre had been built, let alone tried out, the Government proposed to recast medical practice and place it *in toto* on a health-centre basis. They declared the health-centre method to be inconsistent with free competitive practice, but they showed great zeal for the salaried method of service before one health centre was in being! This had been described as the translation of a free profession into a branch of local government service. Whatever might be thought about methods of remuneration, as a profession they could not accept such translation of status. (Loud applause.) Central and local government might be a sound and delightful theoretical concept of political science, but some of them knew from experience that the calibre of membership of local authorities would not justify the handing over to them of personal domiciliary and other medical practice. He reminded the meeting of the action of the L.C.C. two years ago in attempting to reduce the salaries of district medical officers because the population of their areas had been denuded by the "blitz," an attempt defeated by the Metropolitan Counties Branch.

Dr. Hill read some paragraphs from the letter sent to the Minister by the Representative Committee on the previous Wednesday, in which the committee made the suggestion that the only really effective way to deal with the whole problem was to remove it from the ambit of the present discussions and to place it before a Royal Commission.

"You need not have any doubt," Dr. Hill said in conclusion, "about the line which the Representative Committee is taking. It is difficult to avoid at this time of great apprehension an emotional approach to these problems, but I ask you to wait awhile and to leave the matter to those who at the moment are speaking on your behalf. We must avoid a repetition of 1912. Let us have no disunion during the next few months. Let us await the Government's White Paper. Trust the people who are doing the talking for you and hold your forces until the time comes, as it may come, for a fight." (Applause.)

Sample Opinions

Some brief speeches were then made by members of the crowded audience. Dr. E. A. Gregg mentioned the sense of dissatisfaction with the spirit of hurry and bustle which pervaded the whole affair. If the Minister found his task made more difficult he had only himself to blame, having committed himself already to the local authorities. Dr. W. W. Fox suggested that the real reason for the hurry was that the Minister in the immediate post-war era might be able to recruit a large number of men from the Services—men who had never been in practice or whose practice had been disorganized because of change in the area—and who would be rather glad to enter such a service instead of having, perhaps, to approach people to finance them in a new practice. Dr. R. W. Cockshut said that any proposal to turn the family doctor into a local government employee would be killed by public opinion.

Dr. P. Inwald said that this comprehensive health service was not being introduced by a revolutionary Government but by a Government whose prevailing political complexion was a deep blue; therefore the pressure of public opinion must have been very great for the Government to have sponsored a scheme of this kind. It would be very foolish of medical men to oppose something that was for the public good. Mr. W. McAdam Eccles said that consultants, like others, desired first and foremost the good of the community. The author of the Beveridge report had paid little attention to that large section of the profession. There were various alternatives: should all consultants and specialists be whole-time officers of a State salaried service, should they be part-time officers, or should they occupy a position of benevolent neutrality? Dr. M. F. Malony said that in the past nobody could have pretended that the medical services of the country were all that was desired from the doctor's point of view. He thought that in certain respects the Minister's proposals offered an improvement. Dr. Joan McMichael cited the Public Health Service and medical service in the Army as examples of devotion to medicine without reference to a cash incentive. Dr. G. de Swiet asked whether the present Representative Committee would become the negotiating committee. He was afraid that when the White Paper was issued the profession would have no choice but acceptance. Mr. P. W. L. Camps considered that the haste of the Government was due to the feeling that they must strike while the profession was divided within itself. Mr. John Sophian asked why doctors, doing a particularly individualistic work, should be the first to be fettered down and nationalized by these unfair means. The Government were taking medical capital and reissuing it at a very much depreciated rate. He described the service to be provided as a "utility doctor service."

Mr. H. S. Souttar said, as chairman of the Representative Committee which was meeting the Minister on the morrow, that he only wished he could carry the atmosphere of that meeting with him. The committee was asking for a Royal Commission, not because it was dissatisfied with the financial terms suggested, but because it was considered that this was not a matter to be settled by simple discussions between officers of the Ministry and small groups of representative people. There was a wider public which must be informed about what was going on. It was not for the Ministry nor for the medical profession to say whether private practice should or should not be maintained; it was for the country as a whole to decide.

The Men on Service

Dr. Hill, in reply, speaking of the attitude of practitioners away on service, said that there was no reason to believe that an experience of three or four years in whole-time service in the Army would leave them with a predilection for that form of service as one to which they would wish to devote the rest of their lives. There was a note of ill-founded optimism in some of the speeches as to what would be possible under a State system in the way of shortened hours, holidays, and refresher courses. If it was true that there were only sufficient doctors in peacetime to do the work of the country, it would not be possible to shorten hours of labour or to make life easier for the doctor until after a generation or two when there was a great accession to their ranks.

The Association was prepared at the right time, with the co-operation of its members, to find out what the public, and their patients, really wanted. If the people wanted a medical service of a particular kind they would get it, but that stage had not been reached. The public did not yet know what was going on. The public, in his belief, would probably demand that the service of the future should be available to 100% of the community, but he did not believe that they were prepared to look to the town hall as the administrative medical centre. The administrative set-up proposed by the Government was timid, incomplete, and based on the central-plus-local government formulae of which so much had been seen in recent years. It was not a genuinely comprehensive service and it proposed measures which would involve interference with the freedom of the doctor-patient relationship. While it might offer lip service to the principle of free choice, administrative reasons would make free choice less and less possible.

The profession was prepared for serious reforms and reorganization of services which might not be acceptable to them all, but the Government proposals went further and aimed at transforming a free profession into a branch of local government service. At this stage he begged them not to consider the issues of salary and compensation but to stick to fundamentals—the administrative set-up, the right of doctors to be heard authoritatively in the administration of a medical service, and their fundamental distrust of a form of service which brought them under a type of administration not competent or equipped to deal with their main problems. "We must steel ourselves for changes which we may not like, but at this stage let us assert in the public interest the fundamental issue of our freedom."

(On page 641 of the Journal *there will be found a brief report of the interview with the Minister which took place on the day following this London meeting.)*

BIRTHS

Morrison—On May 13, 1943, at Moraig, Stirling, to Nan, wife of Lieut-Col J E Morrison, R.A M.C., of Williamfield, Stirling, a son

Robertson—On May 7, 1943, to Rosemary (*née* Malim) and Dr. Patrick A M Robertson, a son, at Warren Hill Nursing Home, Woolston, Warrington.

Temple.—On March 30, 1943, at Birkenhead, to Kathleen Mary, wife of Capt. R J D. Temple, R.A M C (M E F), a son (Ian Dunbar).

A medical woman is required for whole-time general practitioner service in a group of Royal Ordnance Factory hostels (residents mainly women). Further particulars from Central Medical War Committee, B.M.A. House, Tavistock Square, London, W.C.1.

Two insurance committees, those of Cheshire and the North Riding of Yorkshire, have adopted resolutions urging that the administration of a national medical service should be in the hands of insurance committees. The North Riding committee also decided to oppose any proposal to hand over the medical services to local government authorities.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MAY 29 1943

INSURANCE ACTS COMMITTEE OF THE B.M.A.

DISCUSSIONS ON THE COMPREHENSIVE MEDICAL SERVICE

A meeting of the Insurance Acts Committee, with Dr. E. A. Gregg in the chair, was held on May 13, when there was a full attendance of 40 members. The committee first considered the resolutions passed by the recent Special Conference at which the Government's invitation to enter into discussions, without commitment, on a comprehensive medical service was accepted. In reply to one Scottish member, who protested against what he considered to be the undue proportion of representatives of consultants and specialists among the Scottish representatives, the chairman pointed out that it must not be assumed that the interests of consultants were necessarily confined to their branch of the profession. The consultant was sometimes chosen because he occupied a position of influence and responsibility in medicine and would align himself with his colleagues in medicine generally.

The chairman also said that, although the Insurance Acts Committee was not a constituent member of the Representative Committee, several of its members were on that committee and it would be kept as fully informed as possible of the course of the discussions. In reply to further questions, he said that the Representative Committee had not yet reached the stage of reporting back, though that might happen soon. There would come a time when it would have to take the views of the profession and the profession would be called upon to determine whether that or another committee should pass to the negotiating stage. A long discussion took place on possible eventualities, but certain of the points mentioned were cleared up when the Representative Committee met the Minister on the following Monday.

The Capitation Fee

In connexion with some recommendations and correspondence relating to further action on the capitation fee the chairman said that the Minister had by implication put aside any question of arbitration. It was agreed by the committee to postpone the consideration of this matter until the next meeting.

A letter was read from the Hull Panel Committee suggesting that an ascertainment be now made in advance of the support which would be forthcoming in the event of negotiations for an increase in the capitation fee breaking down The chairman said that he thought it was desirable to find out how many members of the profession would obey a request to refuse service.

After a discussion of all the bearings of the subject, it was agreed that the matter be considered at the next meeting of the committee, when a draft letter would be available for criticism.

Pension and Insurance Scheme for Practitioners

It was reported that, following a discussion with representatives of the insurance companies on outstanding points, the executive committee had authorized a communication to the companies informing them that, subject to the inclusion of the civilian war risk clause under the previous scheme, together with an undertaking that the scheme in its final form would not be offered to any other body of medical practitioners, the committee was prepared to enter into an agreement for the operation of the scheme proposed in a letter, on behalf of the three companies, from the Legal and General Assurance Society. A communication had since been received from that society intimating that all policies, including full benefits (pension, family provision, and disability) issued under the revised scheme, would contain a special condition relative to war risks. The chairman said that he thought congratulations were due to those who had carried through this piece of business.

Medical Records of Men Discharged from the Forces

It was reported that the question of access to medical records of men discharged from the Forces on medical grounds was still under discussion with the War Office and the Ministry of Pensions. One member of the committee stated that insurance practitioners could on application obtain more information about a man's disability, but the methods whereby this information was afforded were not uniform.

Medical Benefit for Juveniles

An explanatory memorandum was laid before the committee on the question of medical benefit for juveniles. In the case of juveniles who joined approved societies the benefit was administered in the same way as for adult members. Juveniles who had not joined approved societies but had surrendered their contribution cards to the Department were registered as members of the Juvenile Deposit Contributors Fund, which had a membership of about 12,000. The memorandum explained how this fund was used, and it was added that, if in any year the fund found itself with an insufficient balance to meet the full cost of medical benefit for all its members, the deficiency would become a charge on the Reserve Suspense Fund. The chairman said that it was not clear that adequate payment was made into the fund to cover juvenile cases, and he would continue to watch the position.

Chemists' Early Closing Hours

The committee, at the instance of one member, considered the effect on insured persons and doctors of the early closing hours now adopted by most chemists. It was pointed out that practitioners were obliged to keep their own surgery hours, but chemists had apparently determined on an earlier closing, which caused great inconvenience to insured patients. The chairman said that this trouble had been experienced also in London, but an undertaking was obtained from the chemists that a rota would be displayed. The thing to be done was to press for action by the insurance committee.

Other Business

The committee agreed to a request from the Somerset Panel Committee that vitamin B_1 tablets should be included in the list of drugs appended to Part II of the Distribution Scheme.

The minutes of the Insurance Acts Subcommittee for Scotland, which had been largely concerned with the proposals for the comprehensive medical service, were noted; and, finally, sitting as the National Insurance Defence Trust, the committee received reports from a number of Panel Committees agreeing to support the proposal to increase the fund to a total of £1,000,000.

Correspondence

Informing the Public

Sir,—Recent correspondence in your columns indicates that an increasing number of medical men are becoming aware of the implications of the Beveridge report and concerned at the methods employed by the Ministry of Health to institute a national medical service. This is very much to the good, for whether or not one favours a State Medical Service an understanding of what is involved in projected legislation is always valuable, and a careful watch on Ministerial behaviour is the privileged duty of every citizen of a democracy. Unfortunately, however, there is little sign either of awareness or concern in other sections of the public or among our Members of Parliament.

Why is it that although doctors are usually popular with their individual patients, yet collectively we are not so with the general public? I think it is because we take our individual patients into our confidence, but never the public as a whole. The time has now come to take the public into our confidence, and I suggest therefore that the profession should take the following steps immediately to acquaint the public with the present situation. The services of first-class expert propagandists should be employed and a flood of propaganda put across by pamphlets, posters, and publications in every newspaper, national and local. Such advertisements would be short and simple, yet striking and pertinent, of the type now published by the Ministry of Food. They would deal briefly with the history of medical practice, the daily work and duties of medical practitioners, the changes effected by the N.H.I., Public Health, and Local Govern-

-ment Acts; in some detail with the fluctuations of the capitation fee, Ministerial rule over doctors and examples of how it has been exercised during the last thirty years; the Public Medical Services, hospital contributory and other schemes inaugurated or supported by the profession; and, finally, the advent of the Beveridge report and the negotiations with the Ministry to date.

The public as well as the profession will then begin to ask, among other things, what is the urgency in the midst of a war, with one-third of our doctors and an equal proportion of our young men and women away in the Services, with taxation already on the topmost notch, to concentrate on the medical provisions—the most expensive, the least demanded, and the most misunderstood—of these revolutionary social proposals, without having any fair time or opportunity for considering them.

We want to serve the public. We want to put our own house in order and be masters in it (within constitutional limits, of course). But time is short. We must stand firm and united. We must mobilize our resources. We must use our strength. We must be prepared for sacrifices. But to win the fight we must enlist public sympathy and support; without them we are not likely to succeed; with them we cannot fail.—I am, etc.,

Liverpool. ARTHUR G. C. FFOLLIOTT.

SIR,—At present widespread discussions are being held among members of the medical profession on the future of medical practice, but there is no guarantee of any official notice being taken of the views of the profession in formulating the national medical service we expect to be brought into existence, in spite of energetic presentation of these views by the British Medical Association to the Government.

As yet there seems to have been no attempt to show the public how vitally they are affected by the steps under consideration, and they are generally unaware of the changes envisaged in the future conduct of medical practice, although any legislation introduced to form such a service will affect them personally more than any legal measure passed in the past fifty years. If we, as practising members of the profession, consider that we are best qualified to judge in what way we can provide the best service for the nation, surely we should make urgent endeavours to show the public the intimate and personal nature of the issues being decided. Our only real voice in legislation is through our Members of Parliament, and it is only by making contact with the public through the Press, public meetings, and otherwise that we can impress our convictions on them and their parliamentary representatives.

The time has surely come for us to shake off our reserve, and we will not lose in dignity by showing confidence in the public, who must have realized by now that we only wish to serve to their best advantage.—I am, etc.,

Hove E. MILLINGTON.

United Action: A Suggestion

SIR,—May I add my voice to those of Dr. Mottershead and Dr. Porteous, who expressed their views so ably and openly in the *Supplement* of May 15 (p. 59). The realization is spreading rapidly throughout our ranks that the proposed conscription of the medical profession—for it means little else—can have only one result—the loss of freedom and the disappearance of all our individual liberty. Our greatest danger—in fact, I think, our only danger—is that we delay too long before we act, relying on our own isolated and uncoordinated feelings to overcome the juggernaut of political plotting. The need for a united front is urgent and compelling or we shall most assuredly lose that freedom which we have struggled to preserve.

Might I therefore suggest the first step toward united action in this matter for those of us who cherish our right as free men to determine our future and the future of our children? What we need is a conclusive and unofficial vote of the profession on the question of State service. My suggestion is that a central address—either a willing individual practitioner, or the B.M.A., or some other suitable agency—should be chosen, and to that address we each should send a postcard with a short, signed statement such as the following:

"I declare that after due consideration of such schemes for State control of the medical profession as have been so far put forward I should refuse all co-operation with them should they be brought into being."

If all of us sent in such a statement and persuaded our professional colleagues to do likewise, I am sure that such a weight of opinion could not fail to bring about the complete overthrow of those political racketeers who threaten by their actions to engulf not only the freedom but also the respectability of the medical profession. Action is now called for. The time for dreaming is past, or, like dreamers, we shall be suddenly and rudely awakened to find that only a memory of our dreams remains. Let us therefore put talk aside and unite, proving to the public and to ourselves that we have a common strength to preserve all that is ours by heritage and tradition.—I am, etc.,

Paisley. A. KENNETH YOUNG

Entry to Consultants and Specialists Group

SIR,—I wonder if my fellow members of the B.M.A. would be interested in this modern version of a Grimm's fairy story.

"Once upon a time in the palmy days of peace and long before the Beveridge report, a fairy godmother known as the B.M.A. instituted a group called the 'Consultants and Specialists Group' of the B.M.A., and gave it a serial number D.45 (B)/1934–5.

"A young surgeon, who was eleven years qualified and who had practised his art for seven years in voluntary hospitals, both teaching and specialist, and for four years in the wicked municipal hospitals, was a little bewildered by the number of societies and groups which were springing up around him, for none of which he appeared to be eligible. He chanced to see an announcement in the columns of his medical journal inviting consultants and specialists who were not engaged in general practice to apply for an application form for membership of the group. Knowing that he was either ineligible or unwilling to join (1) the Society of Medical Officers of Health; (2) the Medical Superintendents' Society; (3) the Medical Practitioners' Union; (4) the Royal College of Nursing; or (5) the Incorporated Association of Hospital Administrators, he realized that no longer was he a forgotten man, for now he had a full-blown society of his own to join.

"Now this young man was something of a freak because he saw good and bad points in both voluntary and municipal hospitals, and he thought his views might be of interest to those less fortunate who had worked in only one particular type of hospital and who were anxious to discuss the pros and cons of a State Medical Service. Unwittingly, therefore, he applied for a membership form, which was duly received together with the compliments of his fairy godmother—the B.M.A. He was embarrassed and humiliated to find that because he was a whole-time public health officer his application would not be considered. He was intrigued by Section 4 of the said application form, which stated that should he not be a consulting physician, surgeon, or obstetrician he would still be eligible for membership of the group if he would state his specialty.

"Visions of 'specialists' in weird and wonderful subjects such as 'specialists in extraction of the first molar tooth' who might be eligible for membership of the group came before his eyes and made him angry, for although he was a Fellow of the Royal College of Surgeons of England and of Edinburgh he held a whole-time appointment as surgeon in a municipal hospital, which automatically rendered him ineligible."

There is a moral in this story which should not be hard to find. If seen and corrected in time it might lead to greater harmony in our profession, which we all follow according to our lights, and ultimately prove of benefit to our patients.—I am, etc.,

Brighton. HAROLD PARK.

*** The Secretary of the B.M.A. writes: The question of the criteria for eligibility for the Consultants and Specialists Group will be reconsidered at the first meeting of the newly elected Group Committee.

A Defeatist Attitude

SIR,—I feel that I speak for many other senior medical students as well as for myself when I say that the attitude of many members of the profession towards the establishment of a State Medical Service is causing grave concern. There is a deplorable lack of initiative evidenced by many of the practitioners, especially those of the older generation. The tendency seems to be to sit back and say: "A State Medical Service is coming whether we like it or not; we can do nothing to stop it and we might as well accept the fact." This, no matter what their opinions of State medical service may be, is a dangerous attitude, which can lead only to slavish and unquestioning acceptance of the terms of service laid down by the Government for their new Civil Service department.

It is a defeatist attitude of the worst type, and one which is becoming much too popular. At present it is put before students, it is put before the meetings of the local practitioners, and it is put before the public through such bodies as the insurance committees. Local and national committees of all kinds are passing recommendations that the provisions of the Beveridge plan—including, in particular, a State Medical Service—be put into effect in this country as soon as possible. The medical profession, although in many cases represented on these committees, is raising no voice in question of the practicability, far less of the advisability, of State Medical Service.

The younger generation, including both undergraduates and medical men in the Forces, has no voice at present. It is their careers and their lives which are being thoughtlessly left to the doubtful mercy of a Government Department. Let those members of the profession who can raise a cry consider carefully before abandoning all hope of managing the profession by their own efforts and without Governmental aid. Let them see that the trust of the younger generation which perforce must meanwhile rest in them is not betrayed.—I am, etc.,

WALTER L. N. PERRY.

Medical School, University College, Dundee

Medical Services and the Public Health

SIR,—Few can be so sanguine concerning the present organization of our health services as Dr. E. C. Atkinson expresses himself to be in the *Supplement* of April 24 (p. 53). While the skill and integrity of individual doctors compare with any in the world, the fact nevertheless remains that our health services are so badly co-ordinated that the country has to pay a high price for the maintenance of our present system.

Many thousands of men were discharged from the Army in the first year of the war on grounds of ill-health. In the Pioneer Health Centre at Peckham 86% of an average group of a comfortable artisan community were found to be suffering from some malady which could be diagnosed. According to the *Lancet* forty million "work weeks" are lost annually because of accidents and disease. Many other facts could be adduced to prove that there is a grave deficiency in the health standard of the country.

Any defence of the present organization of our health services is an acquiescence in the perpetuation of this undesirable state of affairs. To suggest that the average practitioner is prepared to accept this position is, I believe, unjust, and certainly it is no service to the country or to the profession to imply that the present state of health of the population is a reflection of the real capacity of the British health services to supervise the health of the community.—I am, etc.,

Edinburgh. S. LIPETZ.

Absent Doctors

SIR,—Many doctors, whether labelled reactionary or progressive, hold the opinion that now is the time to plan a national health service, but that after the war is the time, unless there is an unexpected social upheaval, to inaugurate such a service, and for the following reasons.

1. The greatest wartime drawbacks in medicine are: (*a*) scarcity of doctors; (*b*) scarcity of specialists; (*c*) lack of hospital accommodation, leading to crowded waiting rooms, crowded hospital out-patient departments, and long waiting lists. Alteration to an organized comprehensive medical service free to all can only aggravate the above conditions and bring discredit on any proposed service.

2. It is unfair to doctors in the Forces materially to alter the status of the medical profession in their absence because: (*a*) They are now otherwise fully occupied and can have little opportunity of group discussion, a vastly different affair from receiving a sheaf of printed matter. (*b*) Most of the younger doctors have no experience of civilian medical practice, and cannot decide wisely now on the best medical service. They would be advised to occupy a brief post-war period in finding their bearings. (*c*) The older doctors will have a nucleus of practice to which to return. Both younger and older will, we hope, receive a gratuity from a grateful country and so will not be in immediate want. There will in any case be plenty for them to do.

I am far from seeking to argue against any change. Surely the course I have advised above is in the best interests of the public and doctors, and is prudent and practical.—I am, etc.,

G. W. M. MACKAY, M.B.

Eighty Fateful Days

SIR,—Just a year ago we were all living under the spell of Mr. Oliver Lyttelton's eighty fateful days. Mr. Ernest Brown's disarmingly simple statement to the House that he contemplates publishing, during the course of the next two or three months, his proposals for comprehensive medical services creates a comparable period of anxiety for all who have the interests of such services at heart.

The private practitioner and voluntary hospital still form the main roots of the system of medical services upon which the people of this country rely. That these roots, which are generally accepted as sound in themselves, do not tap with equal success all strata of the community is a circumstance which may or may not be treated by the radical operation of severing the private and voluntary portions. On evidence so far available it appears that decisions likely to favour this radical procedure are being formulated by politicians. That being so, I humbly submit that the profession should be praying as it has never prayed before that the Lords of Council be endued with "grace, wisdom, and understanding." I would hope, too, that in their ears would ring certain words which Lord Brougham addressed to the House of Lords in debate on the educational system: "It behoves us to take the greatest care how we interfere with a system which prospers so well of itself; to think well, and long, and anxiously, and with all circumspection and all foresight, before we thrust our hands into a machinery which is now in such a steady, constant, and rapid movement; for if we do so in the least degree incautiously, we may occasion ourselves no little mischief, and may stop that movement which it is our wish to accelerate."—I am, etc.,

IAN E. MCCRACKEN.

Newcastle-upon-Tyne

The G.P.'s Wife

SIR,—May I write in support of Mrs. St. Clair Mackenzie's letter (April 10, p. 48). She has my entire sympathy, but may be interested to hear of the plight of another G.P.'s wife.

Saddled with a large, old-fashioned house and without maids (a woman for a few hours to help with the rough work in the early morning), I am marooned at home all day. The door bell rings on an average 70 times daily (sometimes more often on market days), and I often have to run downstairs to answer it. All cooking, bookkeeping, door and telephone answering, helping in dispensary, washing, ironing, dusting, etc., is done by the G.P.'s wife, who has two children, luckily of school age. Cooking is distinctly difficult; for instance, if pastry is attempted, it usually means doffing apron and washing hands several times to answer the door or 'phone.

There are three very busy surgery "hours" in the house daily and medicine to be handed out in between. Dinner is at 8.30 after the last surgery; then come the constant drudgery of washing up, laying the breakfast, black-out to be done, ending with the booking, which is usually completed about 11.30. There is no leisure; we are never able to go to the cinema, etc. The front-door bell is being extended to sound in the garden to enable the doctor's wife to weed, cut the lawn, etc., in odd moments.

Before the war we had three maids and a charwoman and a dispenser-receptionist; now the practice is far larger and we have no maids or dispenser. When illness creeps into the doctor's home, or spring cleaning, or sending out the quarterly bills—all these I leave to the imagination!—I am, etc.,

Leominster. KATHLEEN THOMPSON.

⁂ This is but one of many letters that have reawakened our sympathy with the wife who keeps the doctor's practice and home running in wartime.—ED., *B.M.J.*

Medical and Sickness Benefit: An Invidious Distinction

SIR,—I should like to draw attention to a great injustice from which panel practitioners are suffering. Insured persons pay in for two chief benefits—medical benefit and sickness benefit, to neither of which they are entitled while in the Services. So far as medical benefit is concerned no contribution is made to keep that alive, although if their health breaks down and they are discharged from the Services they are immediately placed on full medical benefit. This is a travesty of insurance which no insurance office would accept and which the approved societies are not asked to accept so far as sickness benefit is concerned. The Services pay in a contribution for each man or woman in the Services, and this is paid to the member's society, although the member has no call upon sickness benefit until discharge.

Why is this distinction made between the two benefits? Because the societies have political power. What is just and fair for one type of benefit should be applied to the other. We should insist that medical benefit is kept alive by some contribution for each member in the Services. The whole principle of insurance is being violated by this injustice to the profession, and we should make it known publicly and insist on the matter going to arbitration.—I am, etc.,

New Malden, Surrey. H. R. CRAN.

FEES FOR MEDICAL EXAMINATION OF N.F.S. PERSONNEL, ETC.

In most areas arrangements have been made under which local doctors are invited to undertake the independent medical examination of members of the National Fire Service, Civil Defence Reserve, the local authority civil defence general services, and the Fire Guard. The examinations are conducted primarily for the purpose of advising the employing authority whether sick or injured personnel are fit or likely to become fit for further civil defence duty, and the fee ordinarily payable for each such routine examination is 5s. In cases in which a medical report asked for involves a specially extensive examination or an exceptional degree of investigation or correspondence on the part of the examining doctor a fee of 10s. 6d. may be paid, and a claim for this higher fee, accompanied by a statement of the special circumstances, will receive consideration.

Diary of Central Meetings

JUNE

23 Wed. Council, 10 a.m.

Branch and Division Meetings to be Held

WEST SUFFOLK DIVISION.—At West Suffolk General Hospital, Bury St. Edmunds, Sun., May 30, 5 30 p.m. Meeting. Non-members of the Division in practice in the area are invited to attend

Meetings of Branches and Divisions

GLASGOW DIVISION

At a meeting of the Glasgow Division, held on April 18, with Dr. Knox in the chair, the Representatives gave a full account of the proceedings of and decisions taken at the recent conference in London. The feeling at the conference, they pointed out, was that the profession throughout the country was averse to local authority control.

The secretary was instructed to call a meeting at an early date, open to all practitioners in Glasgow, to re-elect representatives to the Local Medical War Committee for the ensuing year.

HYDE DIVISION

At a recent meeting of the Hyde Division the following resolutions were carried unanimously:

1. That the Minister of Health be requested not to publish to Parliament or the Press his "general statement of proposals" until they have been considered and agreed by the profession.

2. That control of any scheme of general medical service should be vested in a corporation or similar body which shall be divorced from political control.

3. That the Lancashire and Cheshire Branch be requested to organize central meetings to consider the Minister of Health's proposals for a general medical service—so that we can arrange concerted action by a large and solid body of the profession.

SOUTH MIDDLESEX DIVISION

At the annual general meeting held on April 15, with Dr. J. Murray Scott in the chair, the following officers were elected: chairman, Dr. A. Anderson; hon. secretary, Dr. J. Leach Brown; representative on Representative Body, Dr. P. W. L. Camps.

The Beveridge report and its implications were discussed, and a subcommittee was appointed to study any proposals affecting the profession arising out of that report.

REGIONAL MEETINGS OF CONSULTANTS AND SPECIALISTS

Attention is drawn to further regional meetings arranged under the auspices of the Consultants and Specialists Group of the B.M.A. as follows:

Region 9 (the geographical counties of Berkshire, Buckinghamshire, and Oxford).—Wednesday, June 2, at 2.30 p.m., at the Nuffield Institute of Medical Research, Woodstock Road, Oxford. The discussion will be opened by Sir Farquhar Buzzard, and not by Dr. A. M. Cooke, as stated in the *Supplement* of May 8 (p. 60).

Region 4 (Leeds C.B. and all geographical county of Yorkshire not within the Sheffield region).—Wednesday, June 23, at 3 p.m. at the Medical School, Leeds. The discussion will be opened by Prof. W. MacAdam.

POSTGRADUATE NEWS

The Fellowship of Medicine announces: (1) M.R C P. course in neurology at West End Hospital for Nervous Diseases, Tues and Fri, 3 p.m., June 8 to July 2 (2) Clinical surgery demonstrations on Wed afternoons at London Homoeopathic Hospital (suitable for final F.R.C.S. candidates).

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p m Medical Clinics, Surgical Clinics and Operations, Obstetric and Gynaecological Clinics and Operations *Daily*, 1.30 p m. Post-mortems. *Mon*, 10 a.m., Course on Special Problems in War Surgery commences. *Tues.*, 10 a m., Paediatric Clinic; 11 a m, Gynaecological Clinic; 2 p m., Genito-Urinary Clinic. *Wed.*, 11.30 a.m, Medical Conference. *Thurs.*, 2.15 p.m X-ray demonstration, Dr Topham: The Biliary Tract; 3 p m, Dermatological Clinic. *Fri.*, 12 15 p m., Surgical Conference; 2 p.m., Gynaecological Conference; 2 p m Neurological Clinic; 2 p m. Sterility Clinic.

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W.—*Brompton Hospital:* Tues and Thurs, 4 30 p.m., M R C P. course in chest diseases. *London Chest Hospital:* Tues. and Fri., 2.30 p.m, M.R.C.P. course in chest diseases. *London Homoeopathic Hospital:* Wed. afternoon, Clinical surgery demonstration. *National Hospital for Diseases of the Heart:* Tues. and Wed, 10 a.m., Out-patient clinics.

EDINBURGH POSTGRADUATE LECTURES.—At Edinburgh Royal Infirmary, *Thurs.*, 4 30 p.m. Dr E. K. Dawson. Mammary Cancer and the Menopause.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—*Wed*, 8 p m Dr I. S. MacGregor: Toxic Blindness.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE.—*Tues*, 5 p m. General meeting of Fellows *Thurs.*, 2 30 p.m Section of History of Medicine *Fri*, 10.30 a m. Sections of Laryngology and of Otology. *Sat* (June 5), 10.30 a m. Sections of Laryngology and of Otology.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.—*Mon.*, 5 30 p.m., First Lettsomian Lecture, by Mr. Lionel Colledge: The Pathology and Surgery of Cancer of the Pharynx and Larynx.

BIRTHS, MARRIAGES, & DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than first post Monday morning to ensure insertion in the current issue.

BIRTH

DICKSON.—On May 15, 1943, to Betty (*née* Wood), wife of David C Dickson, F R C.S Ed.; at Upsall Grange, Nunthorpe, Middlesbrough, a son

DEATHS

ARTHUR.—On May 15, 1943, at Uxbridge (late of Ealing), David Arthur, M.D., D.P.H., aged 86 years.

BUTTERWORTH.—On May 23, 1943, after a long illness bravely and cheerfully borne, at the home of her daughter and son-in-law, Easedale, Prestbury, Cheshire, Charlotte Maud, the dearly-loved wife of Dr. J. J Butterworth, late of Southlands, Eccles Interred at Peel Green Cemetery on Wednesday, May 26

MARTYN-CLARK.—At Luton, Walter Ireland Martyn-Clark (aged 60), late of Nigeria and Gold Coast Medical Services.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JUNE 5 1943

FUTURE OF CONSULTANT AND SPECIALIST PRACTICE

MEETING OF CONSULTANTS IN LONDON

A meeting of members of the metropolitan region of the Consultants and Specialists Group of the B.M.A. was held in the Hastings Hall of B.M.A. House on May 19, and was well attended. The purpose was to consider the implications of the Beveridge report and the future of consultant and specialist practice. The chair was taken by Mr. H. S. SOUTTAR.

Dr. G. C. ANDERSON, Secretary of the Association, said that the first approach to this subject must be to appreciate that Assumption B of the Beveridge report meant a form of comprehensive service which was intended to cover 100% of the community. Was the medical profession prepared to accept that? If Parliament decided that the people of this country wanted a service which applied to everyone, was it right that the profession should raise objections, provided that the terms and conditions of the service were satisfactory? What was meant by the word "comprehensive"? Assuming that the service was to be administered by one central Government Department, was it right that the various health functions carried on by other Government Departments—the Ministry of Labour, the Post Office, the Ministry of Supply, the Mines Department, the Board of Education—should be left in their hands? Should not "comprehensiveness" apply from the centre outwards? All these civil health functions should be handed over to the one central authority. If that was not done it meant that the Ministry of Labour would continue to look after industrial hygiene, the Mines Department rehabilitation centres, and so on. The Ministry in charge of the comprehensive service must have available to it adequate medical advice. This meant the setting up of an Advisory Medical Council which would be able to initiate proposals as well as to deal with matters that the Ministry itself had referred to it, and it would be able to issue a report of its own for public consumption and for Parliament should the Minister take an opposite view to his advisers. In addition the Ministry proposed the setting up of some sort of medical board with executive functions to deal with such matters as superannuation arrangements, refresher courses, and so forth. He did not think there would be much quarrel with the Ministry concerning the central administrative fabric, provided an agreed definition of functions could be secured.

Local Machinery

When it came to the local machinery the situation was less clear. The interim report of the Medical Planning Commission suggested that it might be advisable to reorganize the whole of local authority machinery, setting up regional councils to cover wider areas than those of the existing local authorities and embracing populations of perhaps 300,000 to 500,000, and on these councils there should be representatives of the medical profession and of the voluntary hospitals. The proposal now emanating from the Ministry was for joint boards composed of representatives of the comprised local authorities, and it was suggested that there might be representation of the medical profession, but apparently it would be of a very slight character. What the Minister contemplated for the general practitioner service as at present advised was eventually a complete whole-time State salaried service. It was true that to begin with a certain amount of private practice would continue, but newcomers into the profession who joined the service would do so on a whole-time basis, and eventually general practitioners would be part of a whole-time State salaried service of the local authority.

So far as consultant and specialist service was concerned, the proposals of the Ministry were extremely nebulous. It was said that they could not be put forward in a more concrete form at this stage because the report of the Goodenough Committee was not yet available. So far as they went the proposals were that appointments to the service would normally be based upon the hospital service of the area. Payment would normally be on a salaried basis with superannuation rates. The service would be part-time or whole-time "according to circumstances." Those employed upon a part-time basis would have the right of private practice among those members of the community who had decided not to take advantage of their statutory benefit. There would be regular in-patient and out-patient work, with consultations also at associated hospitals, health centres, or, in some cases, the homes of the people. The Association desired the view of consultants and specialists on this question of employment by salary.

The voluntary hospital, while it would retain its autonomy under the new proposals, would receive part of its income direct from the local health authority. The suggestion of the Ministry was that the remuneration of staffs below the grade of assistant surgeon and assistant physician would be on a whole-time basis, and, of course, the medical staffs employed by the municipal hospitals would continue to be employed by them and paid by the local authority.

Such was the position until a day or two previously. But the Representative Committee had during that week met the Minister and put forward its objection to the proposals so far emanating from his Ministry. Indeed, it had asked for a Royal Commission, believing that that was perhaps the best way out of the impasse. After discussion the Minister gave an assurance that these present proposals would be, in his own words, "put in the discard," and it had been agreed to resume consultations with his officers in the hope that the whole situation might be reviewed in a manner perhaps more acceptable to the profession. These discussions were about to begin on the following Monday. In due course the Minister would produce a White Paper which would embody his own conclusions after consultation with the representatives not only of the medical profession but of the local authorities and of the voluntary hospitals. The medical profession (Dr. Anderson continued) was in no way committed by the present discussions. They were entirely non-committal. When this White Paper was forthcoming ample opportunity would be given to the medical profession to pronounce its verdict upon the proposals.

He concluded with a short description of the machinery which the Association had elaborated in order to obtain the views of the consulting section of the profession. In 1934 a Consultants and Specialists Group Committee for England and Wales was set up on the instruction of the Council and at the request of a number of members of the Association who were practising exclusively in a consultant or specialist capacity. The country was divided into fifteen regions. At the present moment elections of a new Group Committee were taking place. The Group was composed exclusively of members in the field of consultant and specialist practice. During the war it had not met very often, but as soon as the new committee was elected it would meet and it would report to the Special Practice Committee, and eventually any proposals would go forward to the Council and to the Representative Body. In this way a synthesis of the opinion of those practising on consultant and specialist lines would be obtained.

The Need for Unity

The discussion was opened by Dr. W RUSSELL BRAIN, who stressed the need for unity in the profession. Medicine, he said, was being thrown into the melting-pot, and what happened in medicine might have considerable influence upon what would happen in other branches of society after the war. With the advent of a State-provided system of medical services paid for by insurance a large part of the financial resources of voluntary hospitals would disappear, and if subscribers were swept away it would be difficult to justify the continuance of lay boards in their present form. Some unification of voluntary and municipal hospitals would probably be reached. The points which seemed to him to be of great importance were: (1) that medical issues should be decided by the medical profession; (2) that a medical committee system should obtain in the municipal hospitals, and medical appointments should be made by such committees, not by lay committees nor by single medical individuals the servants of such committees; (3) a doctor who had attained a position of responsibility in any service must be free to treat his own patients in any way that he thought right; (4) (a point of some value) any doctor who might be paid by the State or local authority, whether in whole-time or part-time service, should be free to sit in Parliament or on the local authority. It would be a great mistake to fix rigidly at this stage the structure of medicine. The aim should be to maintain the utmost possible elasticity with the greatest power to evolve in whatever direction events demanded.

Dr. **GEOFFREY BOURNE** said that medical science and practice must be free from politics, local or central. On the question of State control of medical science no compromise should be possible. There must be freedom of speech and criticism. As for remuneration, it was right to ask for such amount as would furnish a certain degree of comfort, because, after all, medicine was a dangerous occupation. In his view a man was of value to the community in proportion to the difficulty of replacing him, and in that connexion they had only to think of the years of study and preparation which went to the making of a doctor. If the country demanded a State Medical Service it must have it, but doctors had a right to insist that such a service should be placed outside party politics. Perhaps, like the Medical Research Council, it might be placed under the direction of the Privy Council.

Beveridge "Defeatism"

Mr. A. **DICKSON WRIGHT** strongly criticized the acceptance of the Beveridge scheme, which he described as defeatism and likely to make "a nation of parasites." The scheme was not the outcome of any popular demand. It was brought out by the politicians, the most frustrated people in the community. "They want to get the whole of the general practitioners in first, and get them discontented, and then they will get us in themselves." While the war had still to be won the nation was in no mood for arguing about or arranging a post-war medical service. He believed the scheme to be "in the nature of Munich" to the Labour leaders. "We belong to a noble profession; we have worked hard and served the country well, and the public is not dissatisfied with us." He pointed to the recent establishment of a State Medical Service in New Zealand as affording a useful commentary on the disadvantages of such an innovation, and he added that he had seen something of State services abroad and had always come home without any regrets.

Mr. **DONALD BARLOW** spoke of the position of consultants in non-teaching hospitals. He suggested that there were far too many teaching hospitals centred in London. If the number were reduced to half a dozen and the remainder were spread over the Provinces, and if non-teaching hospitals were allowed to take over senior students who had already received their groundwork, it would be a great advantage.

A Ten-point Programme

Sir **JAMES WALTON** put forward three assumptions which he thought must be accepted: that a national medical service was essential, that it must be run either by compulsory insurance or by taxation, and that it must be available to every member of the community. In order to run a service which would afford adequate medical treatment for the whole nation and would maintain the present high standard of medicine and surgery, ten points were essential (others were matters of detail):

(1) That the central control must be in large part medical

(2) That a regional system must be adopted, and the control of this regional system must again be in large part medical.

(3) That the higher posts in the service must be professional as well as administrative.

(4) That medical matters in all hospitals must be controlled by a medical committee

(5) That there must be complete freedom of publication and discussion. (In the last issue of the *British Journal of Surgery* one of the best-known surgeons in the country had to acknowledge permission to publish from an administrative medical officer, a thing which should not be necessary.)

(6) That there must be a unified hospital system.

(7) That there must be free promotion of medical and nursing staff from one hospital to another.

(8) That there must be an accepted standard for all consultants. (The three Royal Colleges had drawn up a standard based on adequacy of training, experience, and knowledge.)

(9) That appointments must be on a salaried basis.

(10) That there must be limited private practice.

He was convinced that these ten points were the essential basic requirements of an adequate national service, and that if a united profession presented them to the Ministry of Health they would be accepted.

Dr **JOHN CAMPBELL** said that he thought the proposals of the Ministry of Health with regard to a general practitioner service to be deplorable. The two solutions were a State Medical Service with a universal salaried basis—a scheme of which he was not enamoured—or an extension of the present insurance system, improved and enlarged as to its benefits, including hospital and consultant services. This could be brought about as a result of better organization, in particular co-ordination between central and distant hospitals.

Mr. **MCADAM ECCLES** said that in addition to whole-time and part-time salaried consultants there might usefully be a third class, described as benevolent neutrals—men and women with knowledge and experience who would be really good consultants and might be called in on occasion, paid either directly by the patient (which would be private practice) or by the State. Dr. **JOHN SPENCER** said that they were all agreed on the ideal of 100% medical service, but not on the machinery whereby it was to be attained. He thought a really efficient service might be built on what they had at present.

In reply to a member of the audience who questioned whether the country wanted the Beveridge scheme to be implemented, Dr. **ANDERSON** said that Parliament must be taken as expressing the will of the people. If Parliament said that the country was to have a comprehensive service (Assumption B) it was the duty of the medical profession to give it, provided the terms and conditions were satisfactory. The questioner here interjected that Parliament was elected eight years ago on entirely different issues and long before Beveridge had ever been heard of, but the **CHAIRMAN** ruled that they could not enter into a discussion on the British Constitution.

Another member of the audience questioned the competence of the Representative Committee, now in discussion with the Ministry of Health, to voice the opinion of the younger practitioners, and said that he would restrict its membership to those under 60. The **CHAIRMAN** said that the Association was asked by the Minister to form a body which would be able for certain preliminary purposes to talk with his officers in a manner representing the medical profession as a whole. With very great difficulty such a body was got together. It consisted of about forty members and included the Presidents of the three Royal Colleges and representatives of similar bodies in Scotland. It was the strongest assembly which could have been obtained. It had already been in consultation with the Minister and his officers for some time. The proposals of the Minister had been laid before it, but on its urgent representation these had been for the time withdrawn, and a small committee from within the Representative Committee had been set up to discuss the matter with the officers of the Ministry at closer quarters in the hope that a really substantial scheme acceptable to the medical profession might be eventually put forward by the Minister in his White Paper. The committee would not enter into any obligations with the Minister as to what the medical profession as a whole was or was not likely to accept without first obtaining the closest consideration by and the final consent of the profession it represented.

GENERAL MEDICAL COUNCIL

SUMMER SESSION

The summer session of the General Medical Council, under the presidency of Mr. H. L. **EASON**, was opened at Hallam Street, London, on May 25, and continued for the three following days. Mr. Henry Wade took his seat as representative of the Royal College of Surgeons of Edinburgh. Sir John Stopford was re-elected Chairman of Business.

The **PRESIDENT** delivered an address from the chair, in which he recorded with regret that Sir Arthur Newsholme had died on May 17. Mr. Alexander Miles on medical advice had been compelled to retire from the Council, and the President paid a high tribute to Mr. Miles's services, especially as a member of the Penal Cases Committee for twelve years. He announced that the Interdepartmental Committee on Dentistry, set up by the Minister of Health and the Secretary of State for Scotland, had invited both the Council and the Dental Board to give evidence before it, and the preparation of this on the part of each body would require serious consideration. Representatives of the Council had given evidence in March before the Interdepartmental Committee on Medical Schools on the lines of a memorandum already approved. During the session the Council would be invited to consider a memorandum prepared by the Executive Committee on a proposal to establish a Register of Consultants and Specialists in the light of such information with respect to the proposal as was at present available to the Council. Convictions of registered medical practitioners reported to the Council by the police in the normal course of administration had begun to include far too many convictions for misuse of petrol under the Motor Fuel Rationing Orders or the Control of Motor Fuel Order. The Penal Cases Committee, before whom these and other convictions of practitioners came in the first instance, had so far only once found it necessary to cause a practitioner to be summoned to appear before the Council in consequence of a conviction of this nature. The President was confident that the Council would share the view of the committee that any such conviction was reprehensible in itself and derogatory to the good repute of the profession. The special privileges rightly accorded to practitioners by the State in this as in other matters implied a special responsibility not to abuse a trust.

DISCIPLINARY INQUIRIES

Wrongful Certification

The Council considered the case of Charles Liddell McHarg, M.B., Ch.B., registered as of Abertillery, Monmouthshire, who appeared on the charge that in the case of eleven evacuated children he had given certificates (in eight of the cases over forty certificates for each child) which were untrue, misleading, or improper. The certificates were given under the Government evacuation scheme, and related to the home nursing of unaccompanied children. The certificate was in the following form:

> I hereby certify that . at present billeted on . . . of . is suffering from . . . and is therefore confined to the billet; that the conditions of the billet appear to me to be suitable for the adequate care and nursing of the child (including the prevention of the spread of any infection); and that such care and nursing are likely to necessitate a material increase in the costs of maintenance, or in the care and attention required.

This certificate had to be sent by the householder to the medical officer of health, and in return the householder received an extra allowance It was alleged with regard to all the children concerned that they were not at any time during the period of several months over which he gave the certificates confined to the billet by illness, and of most of them that they were throughout the period, except for short absences, in regular attendance at a public elementary school.

The complainants, for whom Mr. Michael Bull, counsel, appeared, were the Welsh Board of Health Mr Oswald Hempson, solicitor, appeared for the respondent. Evidence was given by several women from Abertillery, who had had billeted upon them the children whose names were mentioned in the case, that Dr. McHarg had never attended the children at their houses, that they had never taken the children to his surgery or authorized anyone else to take them, and during the time the children had been in their houses they had never suffered from the complaints—chiefly scabies, whooping-cough, and mumps—which were entered under their names in the certificates.

Dr. McHarg gave evidence in his own defence. He said that during the period covered by the complaint—August, 1941, to May, 1942—between 2,000 and 3,000 children came into his district. A number of them were suffering from various complaints, chiefly scabies, and as medical attendant of some of the people with whom they were billeted he saw a large number of these children from time to time. There might have been cases which he did not personally interview when signing the certificate, but as the form was brought to him with the name of the householder already filled in and had been issued from the billeting office, he assumed that inquiries had been made into the case by the billeting officer. At the time there was an acute shortage of doctors in the district, and he was working very hard. He alleged that certain women, in order to get the allowance, had brought children to him under false names, and indeed two women had been prosecuted and had admitted the offences, and during the hearing of these cases the lack of check or investigation at the council offices, to which the certificates were sent, was commented upon by the justices. Many of the women who had children billeted on them were out at work, and he did not think it strange that the same woman should appear with several children; he assumed that she was acting the part of a neighbour. The children were brought to the surgery and he assumed that they were those named in the certificates and acted in good faith. With regard to some of the children he was told by those who brought them that they were being treated at the school clinic, and when he suggested that the forms should be signed by the school doctor he was told (again by the women) that that officer was not allowed to do so and had asked them to see their own doctor. The women had taken an unfair advantage of a busy practitioner.

In the cross-examination of Dr. McHarg the following passages occurred:

How is it that you signed numerous certificates without seeing the children?—I saw them at frequent intervals. You are not supposed to see them every week; at least it does not say anything about it on the billeting note.

Do you think it is safe to go on issuing certificates at the rate of just over one a week without examining these children?—No, but take the matter of scabies; it will not clear up in a week.

So once you were satisfied that a child had scabies you would sign certificates at any time?—Within a reasonable time.

What do you call a reasonable time?—Three or four weeks.

Did you check up when the child had been last to see you?—I used to look at the child.

But sometimes the child was not there. Did you keep any record of what you had entered on your certificates?—No.

Had you kept any record of the dates on which you saw the children?—No, but I wish you to understand that it is not a London practice.

You had not any system either of interviewing or of examining the children on each occasion when you gave a certificate nor any system of keeping check on what occasion you had last made an examination?—I have told you already that it would be impossible owing to the pressure of work.

Would it be correct to say that in any given case you might have gone on signing certificates for months on end?—Not months.

You say in the certificates that the conditions of the billet appeared to be suitable for adequate care and nursing?—Yes.

And you had never been inside the billets?—Some of them, yes.

How many years before?—Oh, well, I do not know. All these houses were pretty much alike.

You knew them from their external appearance, but architecture is not the same thing as suitability. One house might be clean and another might be verminous?—I do not think many are like that in Abertillery.

You do not "think," but you were certifying?—Yes.

Mr. Hempson read a number of testimonials from medical men in South Wales and elsewhere testifying to Dr. McHarg's high character and the probity with which he had conducted his practice. After deliberation *in camera* the Council found the facts alleged against Dr. McHarg proved to its satisfaction, and that in respect of the facts so found he had been guilty of infamous conduct in a professional respect. The Registrar was instructed to erase from the *Medical Register* the name of Charles Liddell McHarg.

Dr. James Davidson, of Streatham, S.W.16, is no longer authorized to have in his possession or to supply dangerous drugs.

Correspondence

Serving Doctors' Practices

SIR,—I am directed by my committee to request that you will publish the following resolution passed by their last meeting.

"This committee, at the suggestion of the Central Medical War Committee and with the approval of the Government, entered into legal agreement with the practitioners in their area to protect their practices during the war and for a year after the termination of hostilities, in the event of their serving with the armed Forces or similar eventualities. As it would be impossible for this committee to carry out the obligations of the agreements if the Beveridge scheme is introduced in their absence, this committee urges the Central Medical War Committee to take all possible steps to prevent the introduction of any such scheme until one year after the termination of hostilities."

—I am, etc.,

KENNETH WATSON.
Hon Sec, Reigate Local Medical War Committee.

A Questionary

SIR,—After many conversations with colleagues it appears that the majority are absolutely opposed to the idea of a State Medical Service, and resent the implication that the profession is in such need of reformation that it must now be changed from top to bottom. Is the public so dissatisfied with the service we give them? No! From whom, then, come all the complaints about our inefficiency? Is there any large mass of abuses in our profession which would not be corrected by an extension of hospital services, by facilities for more frequent postgraduate study, and, possibly, by the extension of the present N.H.I. scheme to dependants of the £250-a-year income group? I make bold to say, "No!"

General practitioners as a class are patient, humble, and inarticulate, not because they are completely uninterested in the conditions under which they work but because they work so hard and so constantly that they have not the time to meet together and make their views and wishes known. Because of this I am afraid that, largely owing to the efforts of a noisy minority, steps may be taken and decisions arrived at that will really be against the interests and wishes of us all. Would it not be possible to find out what medical men want by circulating a questionary framed somewhat as follows:

1. Do you think the nation is adequately served by the present method of private and N.H.I. practice or do you think some new form of medical service should be set up?

2. If you favour the establishment of a new type of medical service, would you prefer a whole-time salaried service or a service where remuneration depended upon a capitation fee?

3. What is your idea of an adequate salary scale or capitation fee?

4. If a State Medical Service is decided upon do you wish for: (*a*) Group practice from a series of health centres? (*b*) Individual practice carried on from your own professional premises, with the provision of additional hospital and laboratory facilities and "general practitioner" beds in extra-hospital wards? (*c*) Administration of such a service by local authorities, as at present constituted, through the M.O.H. and his staff? (*d*) Administration by the Ministry of Health through regional authorities? (*e*) Administration by a committee equally representing G.P.s, hospital staffs (including nurses), and local authorities?

5. As the B.M.A. agreed in essence not to oppose the establishment of a State Medical Service if all the other provisions of the Beveridge scheme were implemented, would you be in favour of refusing to work any such State service if it became apparent that this was the only part of the Beveridge scheme which the Government proposed to implement?

If we got answers to these questions we should have a clear picture of the wishes of the profession as a whole, and if it was apparent that the majority wished to fight against any encroachment on professional privileges and freedom, then the B.M.A. should lead us into the fight without fear or shrinking. If, as a profession, we attain unity nothing can be imposed upon us from above unless we approve of it. We must not lose sight of this fact.—I am, etc.,

Wolverhampton. VICTOR RUSSELL.

Trust the Politician?

SIR,—The impasse into which the medical and allied professions and occupations are being driven by the political sheep-dogs calls for an immediate powerful and decisive counter-offensive. Assumptions are broadcast and accepted without demur, but one assumption has not, so far, been publicly questioned, and that is the veracity and integrity of politicians. One is tempted to ask, with adequate reason, whether one can trust the spoken or written word of any living politician. We have been used as the bait for political blackmail before, admittedly on policies conceived in the best national interests. However, our collective lack of practical organization and executive ability, together with the tenets of our national political system, have caused us to be the unwilling and grumbling sufferers; a misfortune in which no thinking person has any real sympathy with us. Our Council has been granted a short respite and a doubtful promise. Let us use the time gained to organize our forces and so achieve unity of thought and action with personal independence.

Criticism that is not constructive is useless; unfortunately constructive criticism is not usually well received, being classed as too disruptive. In these times, however, any plan is worth considering in the hope that something useful will materialize. I am prompted to suggest that the British Medical Association should be converted into a real B.M.A., a British Medical Alliance of all branches of the profession, its recognized auxiliaries, and allied occupations. The British Isles are small; the world is small; we still have and will continue to have an Empire. Communication in ordinary times will be rapid. Why not anticipate the inevitable and form a British Empire Medical Alliance?—I am, etc.,

London, N 11. RICHARD H. MOORE.

Noble, A. C. Ritchie, G S. Robertson, S. H. Roe, J. H B. M Rowlands, T. D. Semple, L. V Sthyr, M H C. White, N. E. Williams.

The surnames of Lieut. W. Brinitzer and War Subs. Capt. J P Cosgrove are as now described and not as stated in *Supplements* to the *London Gazette* dated March 30 and April 30 respectively.

The initials of Lieut. A. C Jones are as now described and not as stated in a *Supplement* to the *London Gazette* dated March 30.

WOMEN'S FORCES

EMPLOYED WITH THE R A-M C

The following M O.s have been granted commissions in the rank of Lieut.: Ethel K Wacher, Marguerite P Elman, Silvia C. Lucas, Elfriede K. J. Paterson, Neith L. J B. Singleton, Margaret O Withoe-Keus.

CONSULTANT SERVICES AVAILABLE TO G.P.s

The Minister of Health thinks it desirable to remind general practitioners of the help that may be available in the treatment of their patients as the result of the redistribution of consultant services provided under the Emergency Hospital Scheme. Owing to the large measure of pooling of hospital resources under the scheme additional consultants may be attached to the local hospital to which a practitioner has been accustomed to refer his patients, or at other hospitals with which this hospital is linked under the scheme and to which patients are transferred in accordance with arrangements made by the Regional or Sector Hospital Officer.

It is suggested that doctors should familiarize themselves, if they have not already done so, with any additional facilities that have thus become available at hospitals in their area, and that they should make as much use of them as possible in appropriate cases. Should any practitioner find difficulty in informing himself of any such facilities the medical officer of health will be able to advise.

It is particularly important in the national interest that doctors should have access to help of this kind in the case of young industrial workers up to the age of, say, 25. If there are any who are failing to respond to treatment as well as the practitioner would wish he may feel that a further opinion would be helpful, and up-to-date information as to the facilities available will prove useful.

PUBLIC HEALTH AND SCHOOL MEDICAL OFFICERS

In a circular (No. 2818) from the Ministry of Health local authorities are required not only to make a return of their public health and school medical staffs but to notify the Ministry of any vacancy that occurs, to get permission from the Department to fill such a vacancy, and approval of the candidate proposed. The attention of doctors who are employed whole-time in public health and school medical work and who are of military age is drawn to the fact that they are reserved in the posts they now hold. If they wish to apply for other posts they must first obtain the permission of the Ministry. Similar permission is necessary in the case of married women who, if they were not married, would be liable for military service. Written application for permission should be sent through the Regional Medical Officer of the civil defence area in which the doctor is working. Local authorities advertising vacancies in the *Journal* should indicate that the appointment advertised has been approved by the Ministry.

BIRTHS, MARRIAGES, & DEATHS

BIRTHS

O'CONNOR—On May 10, 1943, at Dublin, to Mary J. Ahern O'Connor, M B, wife of Peter J. O'Connor, solicitor, Waterford, a daughter.

RUSSELL—On April 22, 1943, at Mullinahone, to Evelyn, wife of Dr. J. J Russell, M O.H, Mullinahone, Co. Tipperary, a son.

VAUGHAN-JONES.—On March 16, 1943, to Maureen (*née* Cooke), wife of Surg. Lieut-Cmdr R. Vaughan-Jones, Royal Naval Air Station, Trinidad, B W.I., a son (Andrew Robert)

DEATH

MACLEAN—On May 29, suddenly, Dr. Finlay Maclean, 60, Grosvenor Street, Stalybridge; beloved husband of Ima Maclean, aged 49 years.

SUPPLEMENT TO THE

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 12 1943

GENERAL MEDICAL COUNCIL
SUMMER SESSION

(*Continued*)

Inspection of Qualifying Examinations

The business before the General Medical Council at its summer session, other than he investigation of disciplinary cases, was ery slight. On the joint recommendation f the Education and Examination Comittees it was agreed that arrangements hould be made as soon as possible for n inspection on behalf of the Council of ualifying examinations held by all censing bodies or examining boards hose examinations. have not already een inspected in pursuance of a recomendation adopted by the Council a year go. That inspection was limited to the xaminations of bodies which have lopted the recommendation of the edical Personnel (Priority) Committee at, as a matter of emergency, students no produce evidence of having com- ted the whole curriculum after not less n 30 months' certified clinical studies l be admitted to the qualifying hinations. Of the 22 licensing bodies he United Kingdom 18 have already oted the recommendation of the rity Committee. Eire was not affected the recommendation, but its five sing bodies have all invited the attence of inspectors at their qualifying ination this summer. It is therefore osed now to arrange for an inspec- on behalf of the Council of the lifying examinations of the bodies ch are not within the scope of the rity Committee's recommendation. reason for this is to enable the ncil to use such information in its ding on any proposals for amendment the educational provisions of the lical Acts.

The "British Pharmacopoeia"

he report of the Pharmacopoeia Com- e to the Council embodied a report e British Pharmacopoeia Commis- in which its chairman, Prof. J. A. n, stated that in further planning for e revision of the *British Pharma- ia* the Commission believed that the cation of a complete new issue d be deferred until after the war, that the practice of publishing addi- s and amendments to monographs appendices, as they became ready, by eans of addenda should be continued. hese addenda should provide for the revision of the *Pharmacopoeia* both from e point of view of the war emergency d also from the general standpoint of he advancement of medical and pharmaeutical science. The preparation of the Sixth Addendum to the 1932 issue has now been completed. The addendum will contain formulae for a series of ointments prepared with an emulsion base. In these new ointments a considerable proportion of fats and paraffins is replaced by water, and a substantial saving in materials and ansport is effected.

DISCIPLINARY INQUIRIES

Wrongful Certificates

The Council considered the case of WILLIAM VINCENT SAINT JOHN SUTTON, registered as of Shadwell, London, who had been convicted at the Central Criminal Court of giving medical certificates to two persons in H.M. Forces and to a person engaged in the National Fire Service, having reasonable cause to believe that the certificates were likely to interfere with or prevent the performance of their duties. He had been sentenced to nine months' imprisonment.

Mr. Winterbotham, the Council's solicitor, said that there were four cases in the indictment, but Dr. Sutton had desired some fifty others to be taken into consideration. It appeared that the authorities had learned that a number of men in East London were getting extension of leave by visiting Dr. Sutton, who practised in a converted shop, which was in a filthy condition, and by paying a few shillings got a certificate stating that they were suffering from a cold or from some minor malady. Dr. Sutton had at first pleaded "Not guilty" to the charges, but afterwards, on the advice of his counsel, had amended his plea to "Guilty." The judge, in passing sentence, described his action as sabotaging the national effort. In defence of Dr. Sutton, who did not appear, a letter was read from his daughter, protesting that the certificates were issued in good faith, and that his plea of "Guilty" was foolishly made because counsel said that if he so pleaded he would be let off with a fine. It was also mentioned that a petition had been sent to the Home Office on Dr. Sutton's behalf signed by 280 persons in the East End.

The Council directed the erasure of Dr Sutton's name.

Convictions of Misdemeanours

The Council considered the case of WILLIAM ALEXANDER STEVENSON WELSH, registered as of Radnor Road, Handsworth, Birmingham, who had been convicted in April, 1942, at Manchester on four charges of obtaining money by false and fraudulent pretences, and sentenced to four concurrent terms of four months' imprisonment. He was also found guilty by a court martial in Dec., 1940, in two cases of conduct to the prejudice of good order and military discipline, and in seven cases of giving cheques without making arrangements for them to be honoured when presented. A further charge was added to the list, that in March, 1943, Dr. Welsh was convicted of obtaining £15 on false pretences, and sentenced to six months' imprisonment with hard labour. In a letter from prison Dr. Welsh declared that all his cheques had been honoured up to within a few weeks, the amounts were small in proportion to his then income, he had had no intention of defrauding anyone, and his difficulties had been the result of mental stress, partly caused by domestic worry.

The Council directed the Registrar to erase Dr. Welsh's name.

The Council considered the case of CHRISTOPHER WHITEHEAD, registered as of Greystone, Co. Wicklow, who was summoned on two convictions: one in July, 1942, at Leicester, of being found drunk, and the other in March, 1943, at Penarth, of obtaining a sum of money by false pretences. On the latter conviction he was sentenced to four months' imprisonment.

After hearing Dr. Whitehead's explanation, the Council, while finding the convictions proved, did not see fit to direct the Registrar to erase the name.

Motoring Offences

The Council considered the case of ERIC LLEWELYN WILLIAMS, registered as of Old Colwyn, Denbighshire, who appeared on the charge that on March 17 he was convicted at Southport of unlawfully using motor fuel for a purpose not mentioned in the application in response to which the coupons were issued, and on the same date of being in charge of a motor car while under the influence of drink to such an extent as to be incapable of having proper control of the vehicle. He was fined £20 for the first offence and £25 for the second, with £2 5s. 6d., witnesses' expenses, and his driving licence was endorsed.

It was stated that he had received a warning previously from the Council. Dr Williams appeared and made apology and explanation and produced evidence of character and good conduct.

The Council found the facts proved, but postponed judgment for two years.

Cases for Postponed Judgment

In the case of PATRICK JOSEPH MOLLOY, registered as of Hoe Street, London, E.17, in which, at the May, 1942, session, a charge of lax certification was proved but judgment was postponed for twelve months, and in that of PATRICK KENNEDY, registered as of South Harrow, in which, at the May, 1941, session, convictions of being in charge of a motor car while under the influence of drink had been proved but judgment was postponed for two years, the Council did not see fit to direct the Registrar to erase the names, both practitioners having satisfied the Council as to their practice in the interval.

Dental Erasure

The Registrar of the Dental Board was instructed to erase from the *Dentists Register* the name of IVOR LLEWELLYN EDMUNDS, registered as care of Lloyd's Bank, Regent Street, London, following convictions of falsification of accounts and embezzlement.

(*To be continued*)

CONSULTANTS AND SPECIALISTS GROUP

Membership of the Consultants and Specialists Group of the B.M.A. is open to those members of the Association who sign a declaration that they are not engaged in general practice in any form, but practise exclusively as consultants or specialists Forms of application for membership may be obtained from the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Correspondence

A Vote of the Profession

SIR,—One of the characteristic features of this controversy is the wide divergence of opinion shown, due to the peculiar caste system of medical practice, in which each member is inclined to regard such problems from his own particular angle. To organize a common front from such divergent types as consultants, colliery doctors, men in big industrial practices, those in fashionable resorts, not to mention the country doctor, will be no easy matter. If a doctor comes to the conclusion that on the whole he would be better off under a State system he will vote in favour of it; if, on the other hand, he is convinced that he would be the loser on the transaction he will certainly vote against it.

In such a case it is a question for the majority to decide by the method suggested by one of your correspondents—a postal referendum. Incidentally, it would be interesting to know what the public think about it all. So far as I can see they show little interest in the matter. One of them said to me: "Trust the doctors to look after themselves"; let us hope he is right.—I am, etc.,

Leicester. E. J. O'SULLIVAN.

Serving Officers' Views of Salaried Service

SIR,—I have recently returned to this country from abroad, where I was on active service at the time that the Beveridge proposals were made public. I should like to put on record the feelings to those proposals of the medical officers with whom I came in contact and the subsequent discussions.

At first there was a feeling of grave anxiety at the absence of immediate response from practitioners at home, who seemed to be too busy to realize that their future livelihood was at stake. Later much consternation was expressed at the outlook of the Press and the public, who seemed to stress that the medical man must be reduced in status and salary to the level of a clerk before any attempt was made to so interfere with any other profession or trade. Many medical officers gave me good reasons why the coal and automobile industries, banking, and shipping have merited prior places in national reform.

I spoke on the subject to a large number of officers in the course of my evacuation to a base hospital, and the general feeling was that *no* action can be too drastic to prevent us remaining after the war full-time salaried servants of the State.

I would like this letter brought to the attention of the Representative Committee. I have no personal axe to grind in general practice; disability from my wounds precludes that.—I am, etc.,

L. H. G. MOORE, M.B., Ch.B.

Birmingham

Dr. A. G. Davies, a doctor in general practice in Cardiff, appeared before the Stipendiary Magistrate on April 21, charged with failure to comply with the direction of a National Service Officer given under the Defence (General) Regulations, requiring him to undertake a resident hospital post. Dr. Davies, who pleaded not guilty, was found guilty and fined £5 and £10 10s. costs. Payment was suspended pending application for a case to be stated.

OPHTHALMIC GROUP COMMITTEE OF THE B.M.A.

A meeting of the Ophthalmic Group Committee was held, under the chairmanship of Dr. O. G. Morgan, on May 7. The question of the fee for ophthalmic medical examination under the National Eye Service was raised again by one member, who urged the enforcement of the guinea fee for all persons whose incomes exceeded £250 a year. He said that the only arguments in favour of postponement were based on the opposition of the approved societies, but if the Beveridge scheme came into effect the approved societies would presumably cease to exist, whereas if the Beveridge scheme were postponed for some years ophthalmologists could not be expected to wait indefinitely for adequate remuneration. In reply it was pointed out that the objection of the approved societies was not to the higher fee in principle but to the difficulty from an administrative point of view of distinguishing between two income groups of insured persons. Ophthalmologists were also reminded that the service was instituted to provide an ophthalmic medical examination for the lower-income section of the community. A motion in favour of the immediate enforcement of the committee's recommendation made in 1941—i.e., that all insured persons with an income exceeding £250 should be required to pay a fee of one guinea for an ophthalmic medical examination—was not carried.

A Post-war National Eye Service

The remainder of a long afternoon session was taken up with consideration of a draft scheme for a post-war National Eye Service. The scheme was amended in various respects and was referred to a number of ophthalmological organizations for their observations. It will then be considered by a meeting of the members of the entire Ophthalmic Group of the B.M.A.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 19 1943

GENERAL MEDICAL COUNCIL
DISCIPLINARY INQUIRIES

(*Concluded*)

Alleged Falsification of Records of Professional Services

The Council devoted one whole day and ts of two other days to the consideration the case of PARAVASTHU GOPAULA SAWMY, istered as of Warrington Road, Whiston, erpool, who appeared on the charge that order to support a counter-claim for a sum £352 for professional services alleged to e been rendered, he had falsified entries his visiting diary so as to make it appear t he had attended the complainant (Mr. G. B. Griffin, L.D.S., of Liverpool) and daughter during certain periods, whereas fact he had not attended them during e periods. It was further complained nst Dr. Sawmy that he had substituted an earlier letter which he had written to . Griffin's solicitors, in which he had ibed her condition as found by him on nation in 1936, another letter, bearing me date as the first, but written much wherein statements were made as to Griffin's condition at that time, and uch statements were to his knowledge e.

complainant was represented by Mr. Cairns, counsel, and respondent by Mr. Paull, K.C., and Mr. G. Blackledge. Cairns said there had been litigation en complainant and the respondent, in the former claimed the return of a f £400, and the latter counter-claimed 52 for professional services. To sup- his counter-claim he produced certain s in respect of attendances on Mr. n in 1939 and on his daughter in 1941. vidence would show that while some- similar services were rendered at a nt time, no services were rendered the periods indicated by the entries. two had for some years been on ly terms, and each had served the the one as doctor and the other as t, without fee. In Nov., 1940, Mr. and his son went to live with Dr. A year later the solicitor for Mrs. asked Dr. Sawmy for a certificate ng treatment which he had given to Griffin for certain injuries in 1936. letters were ignored, but eventually wmy replied that in his recollection uries were trivial and that Mrs. Griffin ven the history of a fall. Six weeks however, the relations between the two having in the meantime become ed, Dr. Sawmy rang up the solicitor aid that he had now found his records treatment given to Mrs. Griffin nearly ears previously, and that he would give more detailed report in substitution for the st. The first was then returned to him, d under the same date, although actually was written some weeks later, he sent a eport to the effect that Mrs. Griffin gave a story of having been assaulted by her usband, and that she had extensive orbital nd wrist lesions, obviously the result of brutal violence.

When the solicitors for Mr. Griffin asked Dr. Sawmy for further particulars of the counter-claim, these were supplied by affidavit, with Dr. Sawmy's diaries in support. It was stated by Mr. Griffin that all Dr. Sawmy's attendances on him ceased before the first of the dates given. The particulars given by Dr. Sawmy were of 104 attendances between April and Sept., 1939. He also claimed for 26 attendances on Miss Griffin between April and June, 1941, consequent upon a Pott's fracture of the ankle, but the evidence of other witnesses would show that Miss Griffin, though she did fracture her ankle, did so in Sept., 1940, and the registrar of the University of Liverpool stated in an affidavit that on certain dates, when according to Dr. Sawmy she was suffering from the initial stages of a severe lesion and was immobilized, she was in almost daily attendance at the university as a student.

Mr. Griffin gave evidence as to the dates and other particulars. In cross-examination he strongly denied that he had carefully fixed this matter step by step to weave a net for Dr. Sawmy. It was a most improper suggestion that he himself had substituted a forged report on his wife's case for the one which Dr. Sawmy had written and had affixed Dr. Sawmy's signature by a rubber stamp to which he had access (It appeared that the original of this letter could not be produced; it had been copied by the solicitors, who said that they had sent it back to Dr. Sawmy)

Dr. Sawmy, in defence, denied all the charges His entries in the diary had been made at the time of treatment. In 1939 Mr. Griffin offered to lend him £400; it was agreed that money was at that time owing to him by Mr. Griffin, and that adjustment would be made later. On four occasions he rendered accounts for professional attendance, but did not press for settlement In Sept., 1941, Mr. Griffin, after a dispute with his wife, came, together with his son, to live with him. It was acknowledged that with lodging as well as attendance he now owed him more than the £400 he had lent, but Mr. Griffin did not want to discuss a settlement at that time because his wife was bringing an action against him. In Dec., 1941, while residing in Dr. Sawmy's house, Mr Griffin found a letter from Mrs. Griffin's solicitors asking for a report on injuries she had sustained as a result of an assault on her by Mr. Griffin in 1936, and Mr Griffin produced a typed letter which he asked him to send in reply to the solicitors. This, Dr. Sawmy said, he refused to do, and a few days later he sent to the solicitors the full report on the subject, describing injuries of a severe kind, and expressing the opinion that they had been inflicted by a brutal form of violence. That was the only report he gave; it was left in the hall for posting at a time when Mr. Griffin still resided in the house, and when the doctor's notepaper, typewriter, and signature stamp were within access.

The diaries were closely scrutinized by members of the Council. Dr. Sawmy, in cross-examination, agreed that not until 1939 did he prepare an account for Mr. Griffin, that for that purpose he had to go back over his diaries for five previous years, and that the only material on which he could make up the account was the rough diary entries. Supporting evidence was given by Sister Rowson, who was Dr. Sawmy's nurse and secretary, and by other witnesses as to dates.

In a closing speech on behalf of Dr. Sawmy his counsel said that these were criminal charges and that the proper course for the complainant would have been to go to a criminal court and then, if a conviction had been obtained, to come to the Council. But if these charges had been brought before a criminal court they would have been thrown out by any judge and jury in the absence of essential witnesses—namely, Mrs. and Miss Griffin. The former was the obvious person to be called concerning the alleged untrue report, and the latter concerning the dates of her injury and treatment, but the complainant had not seen fit to place either of them in the box. It was true that the registrar of the University testified that Miss Griffin was in attendance there at the time when, according to Dr. Sawmy, he was attending her for a fractured ankle, but might she not, with the leg support he furnished, have succeeded in attending her classes? It was suggested that the diaries had been written up after the quarrel between the two men, but extracts which he read, in which attendance on the Griffins was sandwiched in with notes of other engagements, seemed to testify to their genuineness. With regard to the report on Mrs Griffin's injuries the circumstances pointed to the substitution of another report pretending to be written by Dr. Sawmy but written without his knowledge.

After the Council had given prolonged consideration to the case *in camera* the President announced that the Council had found the facts proved to its satisfaction, and that in respect of the facts so proved Dr. Sawmy had been found guilty of infamous conduct in a professional respect, and the Registrar had been instructed to erase his name.

Complaints relating to Certificates

The Ministry of Labour and National Service brought complaints against two practitioners in Wales for untrue certification. One of these was DAVID WASHINGTON EVANS, registered as of Llantwit Fardre, Glamorgan, against whom it was alleged that he had given a certificate stating that a factory employee was suffering from a bilious attack and unable to follow her employment when in fact he had not seen or examined her on that date or on any approximate date. The girl in question stated that she was prevented from going on night work on Dec 30, 1942, by reason of a bilious attack. A fortnight later her employers insisted on a doctor's certificate to explain her single absence, and her mother obtained it from Dr. Evans, who had attended her for the same complaint in the past, although he had not done so for some months previously.

Dr. Evans admitted that he did not see the young woman on the night in question, but he had seen her on various previous dates for subacute appendix or bilious attacks. He had known the family for fifteen years, and had always found them absolutely and sincerely honest, and when the mother came to ask for the certificate he trusted her word and gave what was required after he had questioned her about her daughter's illness. The certificate was given in a modified form and was not intended in any way to mislead; he believed the manager of the factory already knew that no doctor had seen the girl on the date in question.

After deliberation *in camera* the Council did not see fit to direct the Registrar to erase Dr. Evans's name.

The second practitioner was ARTHUR HINES, registered as of Trehafod, Glamorgan, who had certified a girl factory employee as suffering from gastritis and unable to follow her employment when he had not seen her on the date of the certificate or on any approximate date. The girl in question told a similar story to the girl in the previous case. She had never been attended by Dr. Hines at any time.

Dr Hines said that the girl came to him fourteen days after the date of her few hours' illness, and stated that her employer insisted on a certificate. He told the girl that he saw no necessity to give a certificate for the few hours in question. He knew the family, who lived within 20 yards of his surgery, and her aunt, whom he saw every day, told him on the day in question that her niece had a bilious attack and was unable to go to work. He gave the certificate when it was applied for, having confirmed the truth of the girl's assertion. No charge was made for the certificate. He knew the girl to be an honest and industrious person. She had lost only one shift—due to this attack—since taking up her employment at a munition factory.

In this case also the Council, after private deliberation, did not see fit to instruct the Registrar to erase Dr. Hines's name.

Case following Divorce Decree

The Council considered *in camera* the case of THOMAS ROLLAND STUART THOMPSON, registered as of the R.A.F. Medical Service, who appeared on the charge that by decree of the Divorce Court he had been found guilty of adultery with a married woman with whom he had stood in professional relationship.

The finding of the Council was that the allegation of professional relationship had not been proved, and therefore the complaint was dismissed.

Correspondence

This Leadership Business

SIR,—In view of Dr. Duncan Porteous's letter (*Supplement,* May 15, p. 60) it appears necessary to remind ourselves that there are obvious dangers associated with the uncritical following of "leaders." The picture of the blind and their blind leaders floundering together in the ditch is an authoritative warning for all time of the risk involved in this procedure. Those to whom old masters do not appeal might profitably contemplate the contemporary scene, and especially the dire circumstances into which the peoples of Germany and Italy have been led by the great national leaders to whom they had entrusted their destiny.

Much of the trouble in the world to-day is due to the fact that peoples have left the determination of national policy to rulers. In other words, they have appointed leaders or allowed leaders to be appointed before defining without any possibility of misunderstanding the destination to which they wished to be led. It is curious that political conduct of this kind excites little comment, whereas an individual acting in like manner in regard to his private affairs would soon find himself under grave suspicion as to his sanity. All this goes to emphasize the fact that the determination of policy—the choice of an objective—naturally precedes the selection of the means to the end in view. There is no place for a leader until it has been decided where one wants to go. Nevertheless, in the present medical emergency someone must take the initiative in defining an objective which is believed to be in accordance with the will of the great majority of the profession. This objective has recently been defined in the following terms:

> Objective: To preserve freedom for doctors as individuals.
>
> (*a*) To ensure receipt of income from different sources: to prevent control of income passing to a single authority.
>
> (*b*) To confine a doctor's sphere to the direct doctor–patient relationship: to prevent the substitution of third party (bureaucratic) authority for this relationship.
>
> (*c*) To preserve personal responsibility of doctor to patient: to prevent the substitution of responsibility to officials for responsibility to patients.

It is now the responsibility of every member of the B.M.A. in favour of this objective—probably the vast majority—to use to the limit the machinery of the B.M.A. which exists to make their policy effective.—I am, etc.,

Bexley, Kent E. U. MACWILLIAM.

SUPPLEMENT TO THE
RITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 26 1943

PITATION FEE AND CIVIL SERVICE WAR BONUS

LETTER TO MINISTRY OF HEALTH

e following is the text of a letter, ted June 21, which has been sent to e Minister of Health by the Insurance s Committee:

EAR SIR,—It is understood that, with ect from June 1, 1943, a Civil Service war us will be payable to civil servants re- ng salaries up to £850 a year.

the Minister's recent refusal to make a me increase in the capitation fee was ly based on the assertion that it was rary to Government policy to make such time increases to those not in the lower me groups, the Insurance Acts Com- ee would be grateful for an assurance its application is now being reconsidered he light of this change of policy.

will be appreciated, of course, that the is net salary, and that a considerably er figure represents the gross income ssery to produce the net income of £850 r with non-contributory pension rights.

Yours faithfully,
(*Signed*) G. C. ANDERSON,
Secretary.

Correspondence

ildford Practitioners' Group

Apart from two rather specialized Sheffield (*Supplement*, May 8, nd [illegible]ologists (*Journal*, June 5, [illegible] 30% and 50% return of [illegible]pectively—little statistical e of individual opinion has been ed so far. It is therefore sug- that the activities of the above may be of interest to your readers, larly in view of Dr. Victor M[illegible]s letter "A Questionary" in the *ment* of June 5 (p. 69).

in of the Group and its Objective

consequence of a meeting of the ford Division on March 14 it red that the Representatives to the sentative Meeting might well be g on the opinion of a few local ts rather than on that of the busy nd file of the Division in general. ermore it was noted from the Secre- announcement in the *Journal* of 20 (p. 359) that discussions be- the Minister of Health and the entative Committee would take not on the basis of any pre- d plan of the Minister but 'from und.'" Accordingly it was de- to obtain an index of individual on from local active practitioners in r to test the above supposition and uce statistical figures "from the nd."

2. Activities

In addition to local circularization tact was made with bodies in 17 er counties, copies of our circular questionary being distributed subse- ntly by request.

3. Result of Questionary

Recently a questionary on the future of medical practice was sent to the 150 active practitioners in S.W. Surrey. The response has been excellent, 140 having replied. Of the remainder, seven failed to reply, two have left the district, and one has died. An analysis of the 140 replies shows:

1. That all practitioners should be consulted before the profession is committed to any policy	99½%
2. For continuation of private practice and freedom from control	96 %
3 For extension of the N.H I.A., subject to adequate capitation fee, to—	
(*a*) dependants of the £250 p a. group	62 %
(*b*) „ „ £420 p.a. „	25 %
(*c*) all members of the community ..	5 %
4. That the "urgency" of the present situation is—	
political	82½%
medical	4½%
both	13 %
5. That the capitation fee for the £420 p.a. group should be adjusted before any further negotiations are entered upon with the Ministry of Health	90 %
6. That the B M A.—	
(*a*) is not representative of the whole profession	90 %
(*b*) as at present constituted, is inadequate to meet the existing dangers to the profession	97½%
7. Capacity in which engaged, of the persons who replied:	
general practice	119
consultant work	14
public health, etc.	7
8. B.M.A. Resolution of February 3:	
for	27 %
against	70 %
abstained from voting	3 %

Conclusion.—The obvious conclusion is that the practitioners in S.W. Surrey are overwhelmingly opposed to a State Medical Service and desire the continuation of private practice with freedom from bureaucratic control (96%).

4. Present Situation

It appears that discussion is taking place on an accepted basis that a "scheme" involving control is already a *fait accompli*. This is not discussion on a basis of review "from the ground," but a point well on the way towards a whole-time State Medical Service, leaving both the public and ourselves in the unenviable position of having to negotiate for a meagre percentage of so-called freedom.

5. General Conclusions and Recommendations

Freedom.—The objective of retaining freedom must be constantly adhered to and every endeavour should be made to confine a doctor's sphere to the direct doctor–patient relationship and to prevent the substitution of bureaucratic authority for this relationship.

Representation.—It is essential to ensure true representation of the majority of individual opinion, and, in order that this may be achieved, representatives (to the Representative Body of the B.M.A.) should be elected who themselves hold the same opinion as that contained in their mandate from this majority.

Defeatism.—This atmosphere of defeatism must be opposed at every opportunity. We know that united resistance against restriction of freedom is not useless.

Unity.—Every effort should be made to obtain unity within the profession and to encourage every member of the profession, if not actually to join them, at least to support the B.M.A. in their activities on our behalf.

"From the Ground."—It is suggested that every Division should take steps at once to obtain statistical figures of opinion on similar lines and acquaint the B.M.A. with their findings in order to afford those taking part in the discussions some concrete evidence of individual opinion.—We are, etc.,

L. B. HARTLEY.
E. E. HEANEY.
G. J. HOLLIS.
W. MERCER.
J. A. PATERSON.
J. O. M. REES.
W. L. WINSLOW SMITH.
G. HUMPHREY WARD.
Also, two Government medical officers, whose names, for obvious reasons, must be omitted.

Guildford.

Sheffield Practitioners' Group

SIR,—In view of the impending reorganization of medical services a mass meeting of general practitioners was called by the Sheffield General Medical Practitioners Group at the Royal Victoria Hotel, Sheffield, on June 4. The meeting was addressed by an eminent gynaecologist, a member of the Royal College of Surgeons, who is also chairman of the Sheffield Division of the B.M.A., by a local Member of Parliament, and by a member of the Representative Committee appointed to discuss the future reorganization of medical services with the Minister of Health. There was an attendance of 163 members of the profession; probably the best-attended meeting of the profession locally for over twenty-five years.

After listening to the addresses by the above-mentioned speakers a lively discussion followed, and the following resolutions were passed without dissent:

1. That this meeting of medical practitioners of Sheffield and district hereby resolves that it will resist to the utmost any attempt to introduce a salaried State Medical Service as recently suggested by the Minister of Health, but that it will freely co-operate in the reorganization of the medical services on the lines set forth in the Interim Report of the Medical Planning Commission.

2. That this meeting further wishes to record that it will not accept any form of local government control in any reorganization of medical services affecting the general practitioner.—I am, etc.,

PHILIP N. GRINLING,
Honorary Secretary.

Sheffield

Certificates and Compulsory National Service

SIR,—Every general practitioner must be overwhelmed with requests for certificates. Most of us, having consciences and the wish to help the war effort to the fullest, spend a considerable amount of time daily in weighing the pros and cons of each individual case, losing patients frequently rather than issuing unwarranted certificates.

Where these certificates relate to appeals against compulsory national service or civil defence work, the National Service Officer (a layman) has the power to decide whether he will accept the certificate or force the appellant to be examined by an independent medical practitioner appointed as referee. This referee can override any certificate, but, having no special qualifications and no knowledge of the person's past history or present environment, he cannot be in a position to judge the case as satisfactorily as the person's own doctor. The whole arrangement is humiliating, unjust, and against all the ethics of the profession.—I am, etc.,

Streatham, S.W 16. HARRIS AVERY.

Medical Resettlement

SIR,—When the war is over a large number of our colleagues now on active service will be returning to this country anxious to enter or to re-enter civil practice. It will be the duty of us at home to give them all the help we can. Most of them will be without capital and without recent experience, and we should consider a practical scheme at once to overcome these difficulties. I would suggest that in every district a panel of doctors willing to take these men and women into their practices should be prepared. After a period of preliminary assistantship it should be possible for them to take up partnerships and to provide the appropriate premiums out of their actual earnings. In this way many who at present know nothing of the conditions and scope of general practice will gain experience which will enable them to decide for themselves whether they are prepared to exchange this for State control of medicine with its manifold disadvantages.—I am, etc.,

High Wycombe DAVID ELLIS.

TYRES FOR DOCTORS' CARS

The B.M.A. has had occasion to bring to the notice of the Tyre Directorate of the Ministry of Supply a number of cases of considerable delay in providing tyres urgently required by doctors. The Directorate are anxious that doctors' applications should be dealt with as expeditiously as possible, and they have usually given prompt assistance through the Regional Tyre Officers when complaints received by the Association have been forwarded to them. They suggest, however, that time would be saved if a doctor, when he is unable to obtain reasonably prompt delivery of tyres for which he holds a permit, were to make direct application to the Regional Tyre Officer, whose address may be obtained from the authorized tyre dealer with whom the tyre application form is lodged.

Dr. J. F. Galloway has been appointed medical officer of health and schools medical officer to the county borough of Doncaster in succession to Dr. R. Watson, who has been appointed medical officer of health to the East Riding.
